ABSTRACT

The problem of electromagnetic radiation and scattering from conducting bodies of revolution, both loaded and unloaded, is considered. The solution is obtained by the method of moments applied to the integro-differential equation, and is expressed in terms of generalized network parameters. Computer programs are given for plane-wave scattering and for radiation from apertures. The programs are valid for solid bodies, zero thickness conductors, and bodies with points and edges. The solution for planar bodies is also a solution for diffraction through apertures in a conducting plane, according to Babinet's principle. Representative computations are given for scattering and radiation from disks, washers, toroids, hemispheres, and cone-spheres.

CONTENTS

I. INTRODUCTION AND SUMMARY

The objectives of this project were to develop practical methods for computing the generalized impedance matrix applicable to the study of electromagnetic radiation and scattering from highly conducting bodies of revolution. Specific topics considered were: (A) Development of a computer program to allow numerical evaluation of the generalized impedance matrix for a conducting cone-sphere of maximum dimension approximately six wavelengths. (B) Application of the impedance matrix to determine the scattering properties of a cone-sphere with and without loading elements on the body. (C) Application of the impedance matrix to determine the radiation and scattering properties of a cone-sphere with antenna slots on its surface.

The project work was performed during the period 1 June 1967 to 30 June 1969. The technical personnel working on the project were Dr. Roger F. Harrington and Dr. Joseph R. Mautz. During the contract period one previous scientific report was written entitled "Generalized Network Parameters for Bodies of Revolution," dated May 1968.[1] Also, one paper entitled "Radiation and Scattering from Bodies of Revolution" has been published in Applied Scientific Research.[2] The material in the above listed scientific report and paper also formed a part of Dr. Mautz's Ph.D. thesis, Syracuse University.[3]

The following is a summary of the research performed during the project.

(A) A general program was developed for computing generalized network parameters for conducting bodies of revolution. The theory and original program is given in the previous report.[1] An improved program is given in this report.

(B) Aperture antennas in conducting bodies of revolution were analyzed, and computations made for body currents and radiation patterns. The theory is given in the previous report,[1] and the computer program is given in this report.

(C) Electromagnetic scattering by conducting bodies of revolution was considered. The theory is given in the previous report,[1] and the computer programs for plane-wave scattering are given in this report.

(D) Radiation and scattering from loaded bodies of revolution was studied, and computations made for representative bodies. The theory and some computations for cone-spheres are given in this report.

(E) The problem of determining the eigencurrents for conducting bodies of revolution was considered, and representative computations were made. Details are not included in this report because only a preliminary study was made.

(F) The problem of synthesizing and optimizing radiation and scattering patterns from loaded bodies of revolution was considered, and representative computations were made. Details are not included in this report because only a preliminary study was made.

II. METHOD OF SOLUTION

The problem is formulated in terms of potential integrals, and the boundary conditions at the body are applied. This results in an integral equation, which is then solved by the method of moments. The matrices obtained thereby can be expressed in terms of generalized network parameters.[4] A general exposition of the procedure is given in a recent monograph.[5] The following is a summary of the theory as it applies to the present problem.

Let $\mathbf{E}^i$ denote the known impressed field and $\mathbf{E}^s$ the scattered field due to currents on the body. Then the total field $\mathbf{E}$ is the sum of the impressed and scattered fields, that is,

$$\mathbf{E} = \mathbf{E}^i + \mathbf{E}^s \tag{1}$$

The scattered field can be expressed in terms of a vector potential $\mathbf{A}$ and scalar potential Φ as

$$\mathbf{E}^s = -j\omega\mathbf{A} - \nabla\Phi \tag{2}$$

where

$$\underline{A} = \mu \oiint_S \underline{J} \frac{e^{-jkR}}{4\pi R} ds \tag{3}$$

$$\Phi = \frac{1}{\epsilon} \oiint_S \sigma \frac{e^{-jkR}}{4\pi R} ds \tag{4}$$

Here S is the surface of the conductor, R is the distance from a source point to the field point, $\underline{J}$ is the surface current on S, and σ is the surface charge on S. The current and charge are related by the equation of continuity

$$\nabla \cdot \underline{J} = -j\omega\sigma \tag{5}$$

The boundary condition requires that the tangential component of total $\underline{E}$ vanish on S. Hence,

$$\underline{E}^i_{tan} = -\underline{E}^s_{tan} \tag{6}$$

where the subscript tan denotes tangential component on S. The problem can now be stated succinctly as

$$L(\underline{J}) = \underline{E}^i_{tan} \tag{7}$$

where L is the integro-differential operator

$$L(\underline{J}) = [j\omega\underline{A} + \nabla\Phi]_{tan} \tag{8}$$

A solution of (7) gives the current $\underline{J}$ on S. Usually we are interested in some functional of $\underline{J}$ which can be computed once $\underline{J}$ is known.

To effect a solution by the method of moments, let the inner product be defined as

$$\langle \underline{W}, \underline{J} \rangle = \oiint_S \underline{W} \cdot \underline{J} \, ds \tag{9}$$

where $\underline{W}$ and $\underline{J}$ are tangential vectors on S. A set of expansion functions $(\underline{J}_j)$ is next defined, and the current on S approximated by

$$\underline{J} = \sum_j I_j \underline{J}_j \tag{10}$$

where I_j are constants to be determined. Equation (10) is substituted into (7), which, because of the linearity of L, reduces to

$$\sum_j I_j L\underline{J}_j = \underline{E}^i_{tan} \tag{11}$$

A set of testing functions $(\underline{W}_i)$ is defined, and the inner product of (11) with each $\underline{W}_i$ is taken. The result is

$$\sum_j I_j \langle \underline{W}_i, L\underline{J}_j \rangle = \langle \underline{W}_i, \underline{E}^i \rangle \tag{12}$$

$i = 1,2,3,\ldots$. The subscript tan has been dropped from $\underline{E}^i$ because the inner product involves only tangential components. We now define the generalized network matrices

$$[Z] = [\langle \underline{W}_i, L\underline{J}_j \rangle] \tag{13}$$

$$[V] = [\langle \underline{W}_i, \underline{E}^i \rangle] \tag{14}$$

$$[I] = [I_i] \tag{15}$$

and rewrite the set (12) as

$$[Z][I] = [V] \tag{16}$$

$[Z]$ is the generalized impedance matrix, and $[Y] = [Z]^{-1}$ is the generalized admittance matrix. The inverse of (16)

$$[I] = [Y][V] \tag{17}$$

gives the coefficients I_j of the current expansion (10), and hence is an approximate solution to the problem.

The impedance elements of (13) are explicitly

$$Z_{ij} = \oiint_S \underline{W}_i \cdot (j\omega \underline{A}_j + \nabla \Phi_j)\, ds \tag{18}$$

where we have used (8) and (9). The subscript j denotes that $\underline{A}_j$ and Φ_j are the potentials due to $\underline{J}_j$ and σ_j. If the two-dimensional divergence theorem is applied to the vector $\Phi \underline{W}_i$ on a closed surface, the following identity results:

$$\oiint_S \nabla \Phi \cdot \underline{W}_i \, ds = - \oiint_S \Phi \nabla \cdot \underline{W}_i \, ds \tag{19}$$

If $\underline{W}$ is thought of as a current, the charge associated with it is

$$\sigma_i = \frac{-1}{j\omega} \nabla \cdot \underline{W}_i \tag{20}$$

Now (18) can be written as

$$Z_{ij} = j\omega \oiint_S (\underline{W}_i \cdot \underline{A}_j + \sigma_i \Phi_j)\, ds \tag{21}$$

Equation (21) is more convenient for computation than (16) because the gradient operation on Φ has been eliminated.

The above formulas have been specialized to bodies of revolution in the previous report.[1] Also given there are representative computations for radiation and scattering from unloaded conducting bodies of revolution. Computer programs and further computations are given in this report. An alternative solution for the case of plane-wave scattering from unloaded conducting bodies of revolution has been given by Andreasen.[6]

The general theory of loaded antennas and scatterers with lumped loads is available in the literature.[5,7] An extension to continuously loaded surfaces will now be given. Lumped loads can be considered

as a special case of continuous loads localized to infinitesimal sections of the surface.

A continuously loaded surface S is defined as one for which the total tangential electric field is related to the current $\underline{J}$ on S by an impedance function of position $\mathcal{Z}$ according to

$$E_{tan} = E^i_{tan} + E^s_{tan} = \mathcal{Z}\,\underline{J} \qquad (22)$$

Now E^s_{tan} is related to the current $\underline{J}$ by

$$E^s_{tan} = -L(\underline{J}) \qquad (23)$$

where L is given by (8). Combining (22) and (23), and rearranging, we have

$$L(\underline{J}) = E^i_{tan} - \mathcal{Z}\,\underline{J} \qquad (24)$$

This reduces to (7) when $\mathcal{Z} = 0$, that is, when S is covered by a perfect conductor. We can now reduce (24) to a matrix equation in the usual way by the method of moments, obtaining

$$[Z][I] = [V] - [Z_L][I] \qquad (25)$$

where [Z], [V], [I] are given by (13), (14), (15), and

$$[Z_L] = [\langle \underline{W}_i, \mathcal{Z}\,\underline{J}_j \rangle] \qquad (26)$$

The solution to (25) for the current coefficient matrix is

$$[I] = [Z + Z_L]^{-1}[V] \qquad (27)$$

Note that this solution is analogous to that for two n-port networks connected in series with the voltage source [V].

The impedance function $\mathcal{Z}$ is zero over those parts of S covered by a

perfect electric conductor. If subsectional expansion and testing functions are used, many of the elements of $[Z_L]$ may be zero when the surface S is partially covered by an electric conductor. In such cases the following alternative solution may be computationally faster. Suppose $[Z_L]$ has some zero rows and columns. Let $[Z_L^r]$ be the matrix obtained from $[Z_L]$ by deleting all zero rows, $[Z_L^c]$ by deleting all zero columns, and $[Z_L^{rc}]$ by deleting all zero rows and columns. Other matrices with the same rows and/or columns deleted will be identified by the same superscripts. Then, multiplying (25) by $[Y] = [Z^{-1}]$, and deleting the appropriate rows and columns, we have

$$[I^r] = [Y^r][V] - [Y^{rc}][Z_L^{rc}][I^r] \tag{28}$$

The solution of this for $[Z_L^{rc}][I^r]$ is

$$[Z_L^{rc}][I^r] = [Y^{rc} + Y_L^{rc}]^{-1}\,[Y^r][V] \tag{29}$$

where $[Y_L^{rc}] = [Z_L^{rc}]^{-1}$. The solution is now given by (17) with $[V]$ replaced by

$$[V'] = [V] + [V_L] \tag{30}$$

where $[V_L]$ is the matrix obtained by adding the appropriate zeros to

$$[V_L^r] = -[Z_L^{rc}][I^r]$$

$$= -[Y^{rc} + Y_L^{rc}]^{-1}\,[Y^r][V] \tag{31}$$

The excitation is thus viewed as the superposition of the impressed voltage $[V]$ plus the load voltage $[V_L]$.

The computations of the next section for loaded antennas and scatterers were made using this second formulation. A problem arises in the case of an open circuit, since then elements of $[Z_L^{rc}]$ may become infinite.

However, $[Y_L^{rc}]$ is still well defined, and may be obtained from $[Z_L^{rc}]^{-1}$ by setting the "infinite" elements to some very large number.

III. REPRESENTATIVE COMPUTATIONS

The graphs of this section are intended to illustrate some of the types of computations that we have made during the project. Computer programs for the unloaded antenna and scatterer computations are described in the next section, and listed in the Appendix. Included in the programs are printer plot routines, so that rough graphs of the computations are available immediately.

All programs have been run on spherical bodies, and compared to the classical eigenfunction solutions for spheres. Far-zone quantities, such as radiation fields, agree very closely (usually within a fraction of one percent) with the classical solution. Near-zone quantities, such as currents on the body, also agree well (usually within a few percent) with the classical solution. Examples of such comparisons are given in the previous report.[1]

The programs have been written to handle correctly the following types of bodies: (A) solid conductors, such as spheres, closed cylinders, (B) zero thickness conductors, such as disks, open cylinders, (C) bodies intersecting the axis, such as spheres, disks, (D) bodies not intersecting the axis, such as toroids, washers, (E) bodies with points, such as cone-spheres, (F) bodies with edges, such as disks and open cylinders, and (G) bodies with corners, such as closed cylinders. The programs have not been written to handle multi-body problems, but the modification required is simple. The accuracy of computations depends on the smoothness of the body and of the excitation. For example, solutions with bodies having points or edges converge more slowly than solutions for bodies with gently curved surfaces. Solutions for localized aperture excitation converge more slowly than solutions for plane-wave excitation.

Solutions involving zero-thickness conductors in the $z = 0$ plane are interesting because they are also solutions to the dual problem of apertures in an infinite conducting screen (Babinet's principle).[8] In particular,

the duality relationship is

$$E_\rho = J_\phi/2 \qquad E_\phi = -J_\rho/2 \tag{32}$$

where J_ϕ, J_ρ is the current on the conducting plate, and E_ρ, E_ϕ is the tangential $\underline{E}$ field in the complementary aperture. A number of computations for the circular disk and aperture were made, and compared to available measurements.[9,10,11] The agreement was within the estimated experimental accuracy.

Figure 1 shows the current on a circular disk of diameter $D = 0.8\lambda$, excited by an axially incident plane wave, as computed by the program of Section V. Note that $J_\rho \longrightarrow 0$ and $J_\phi \longrightarrow \infty$ at the edge, as theory predicts. Figure 2 shows the computed bistatic radar cross section patterns for the same disk. The curve labeled $\sigma^{x\theta}/\lambda^2$ is the E-plane pattern, and that labeled $\sigma^{x\phi}/\lambda^2$ is the H-plane pattern. (See the previous report[1] for a discussion of the notation.) By duality, the same patterns are also power patterns for the field diffracted through a circular aperture in an infinite conducting plane excited by a plane wave at normal incidence.

Figure 3 shows the computed current on a circular washer of outside diameter $D = 2.4\lambda$ and inside diameter $d = 0.8\lambda$, excited by an axially incident plane wave. Again J_ρ and J_ϕ have the expected behavior at the edges. Figure 4 shows the computed bistatic radar cross section patterns for the same disk. By duality, these patterns are also power patterns for the field diffracted through a circular annulus in an infinite conducting plane excited by a plane wave at normal incidence.

Figure 5 shows another example of a bistatic radar cross section pattern for a body of revolution excited by an axially incident plane wave. It is for a toroid of mean radius $R = 0.5\lambda$ and circular cross section of radius $r = 0.12\lambda$. The previous report[1] showed bistatic radar cross sections of cone-spheres, as well as the currents on the bodies. These computations are repeated in the computer print-out of Appendix B.

Figures 6, 7, and 8 show some examples of radiation from rotationally symmetric apertures in bodies of revolution. Figure 6 is the power gain pattern for a circular disk of diameter $D = 1.6\lambda$ excited by a voltage across

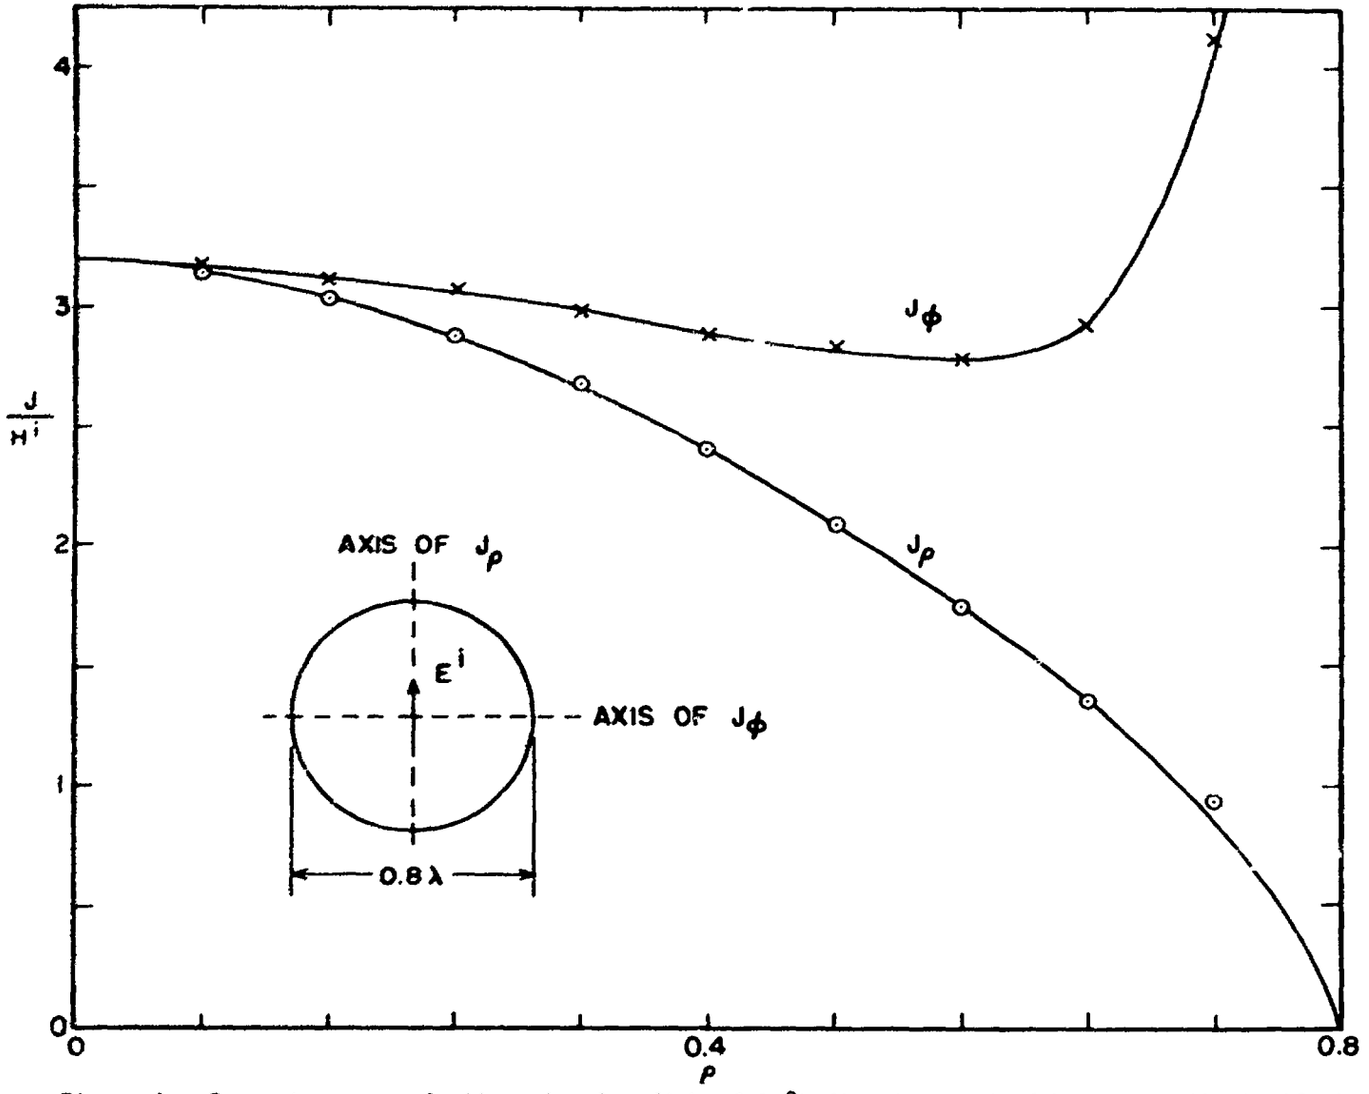

Figure 1. Current on a conducting circular disk of 0.8λ diameter excited by an axially incident plane wave.

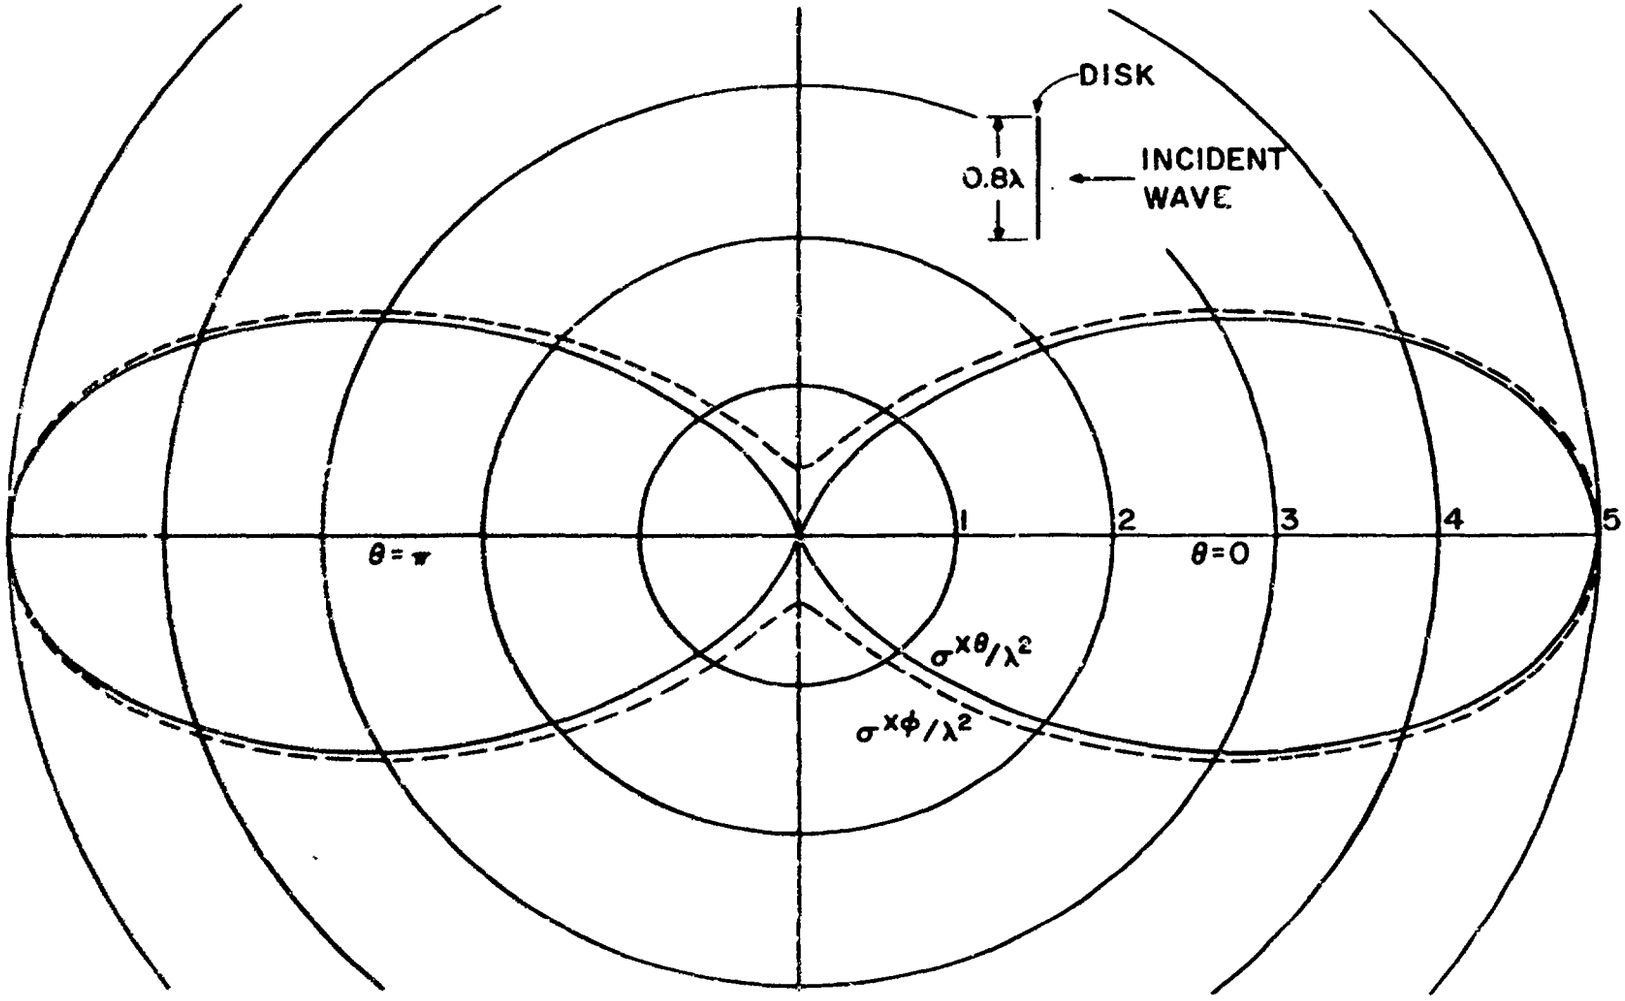

Figure 2. Bistatic radar cross section for a conducting circular disk of 0.8λ diameter excited by an axially incident plane wave. The E-plane pattern is labeled $\sigma^{x\theta}$ and the H-plane pattern $\sigma^{x\phi}$.

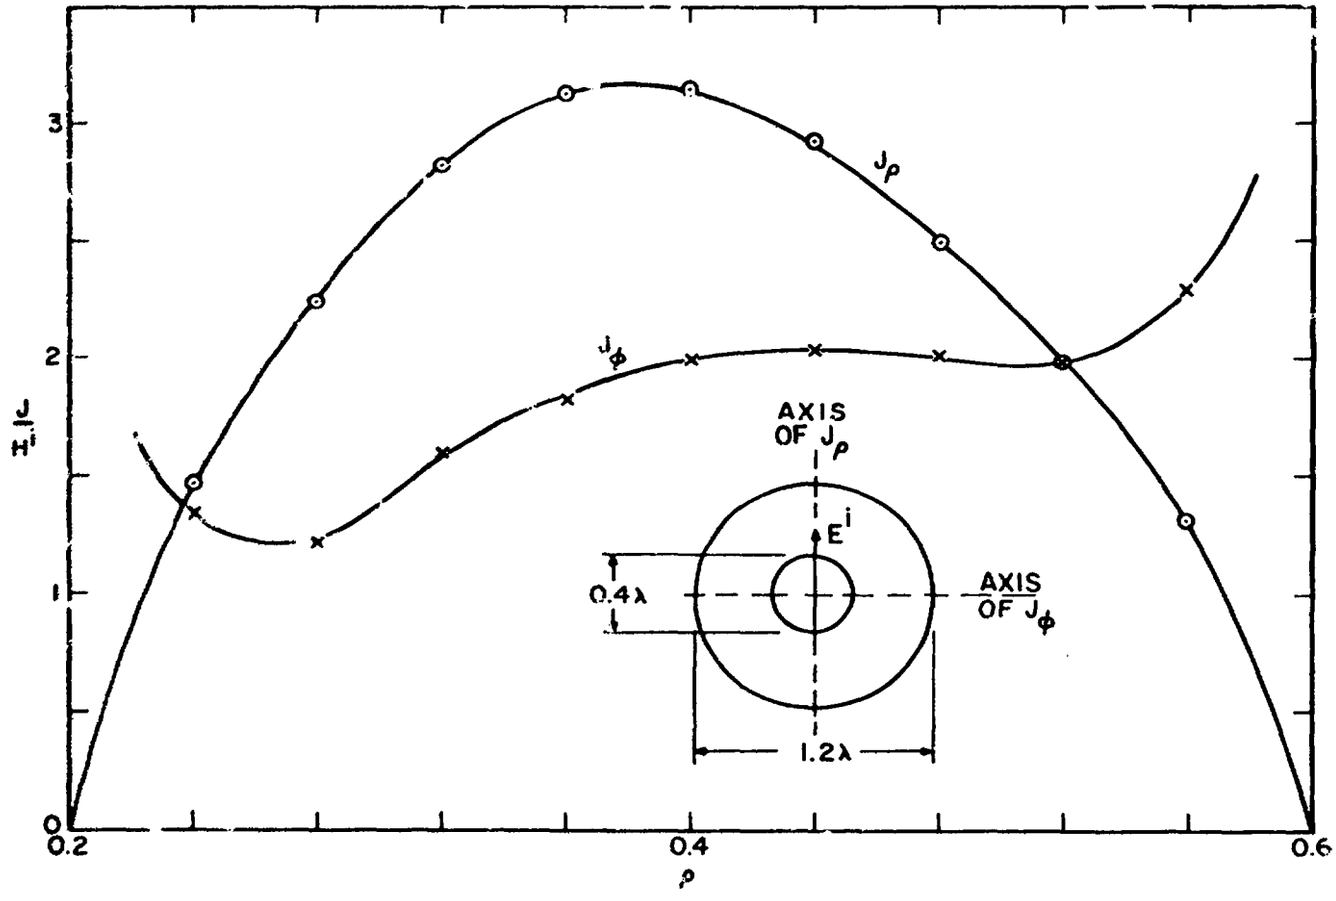

Figure 3. Current on a conducting circular washer of 1.2λ outside diameter and 0.4λ inside diameter, excited by an axially incident plane wave.

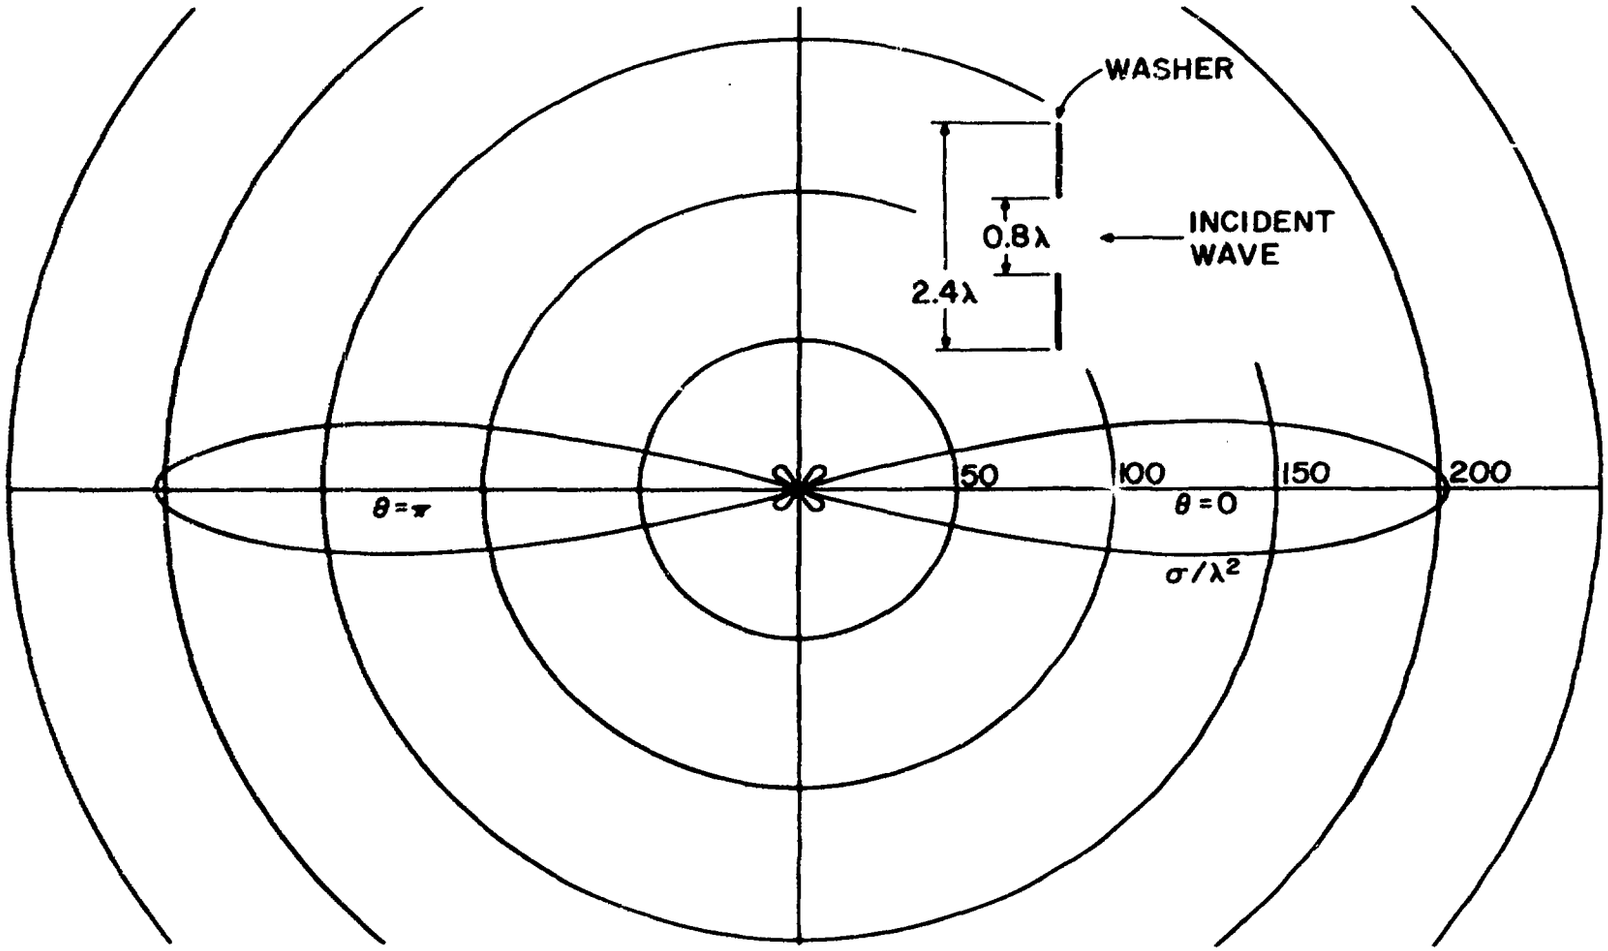

Figure 4. Bistatic radar cross section for a conducting circular washer of 2.4λ outside diameter and 0.8λ inside diameter, excited by an axially incident plane wave. E-plane and H-plane patterns are almost the same.

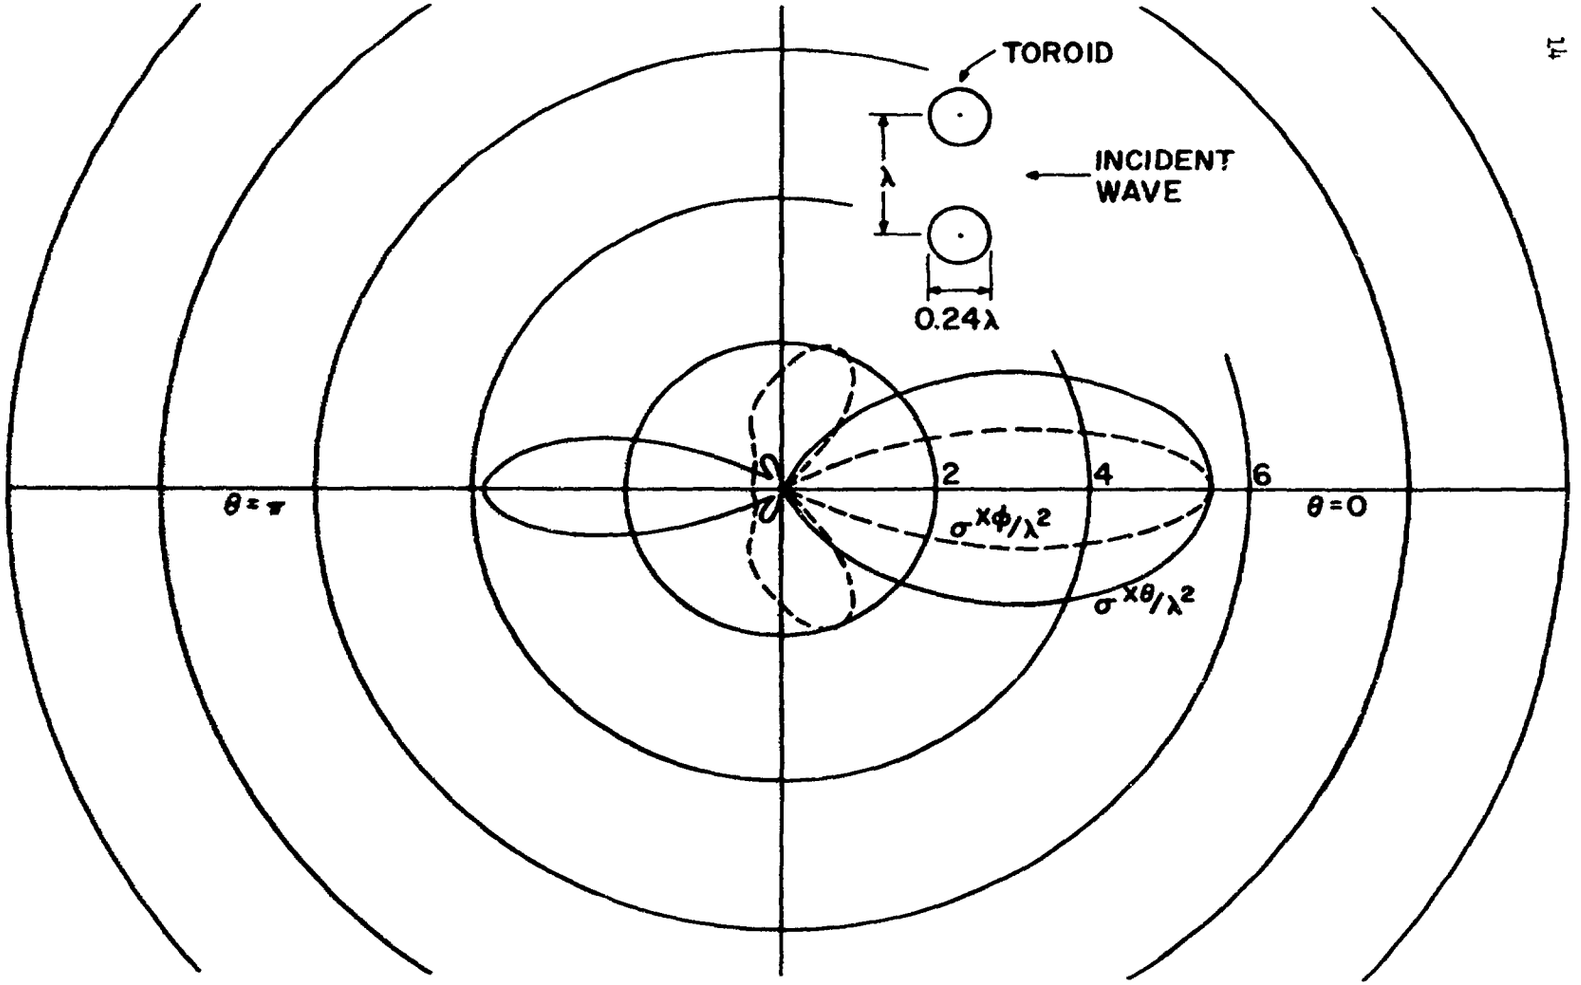

Figure 5. Bistatic radar cross section for a conducting toroid of 1λ mean diameter and 0.24λ cross-sectional diameter, excited by an axially incident plane wave. The E-plane pattern is labeled $\sigma^{x\theta}$ and the H-plane pattern $\sigma^{x\phi}$.

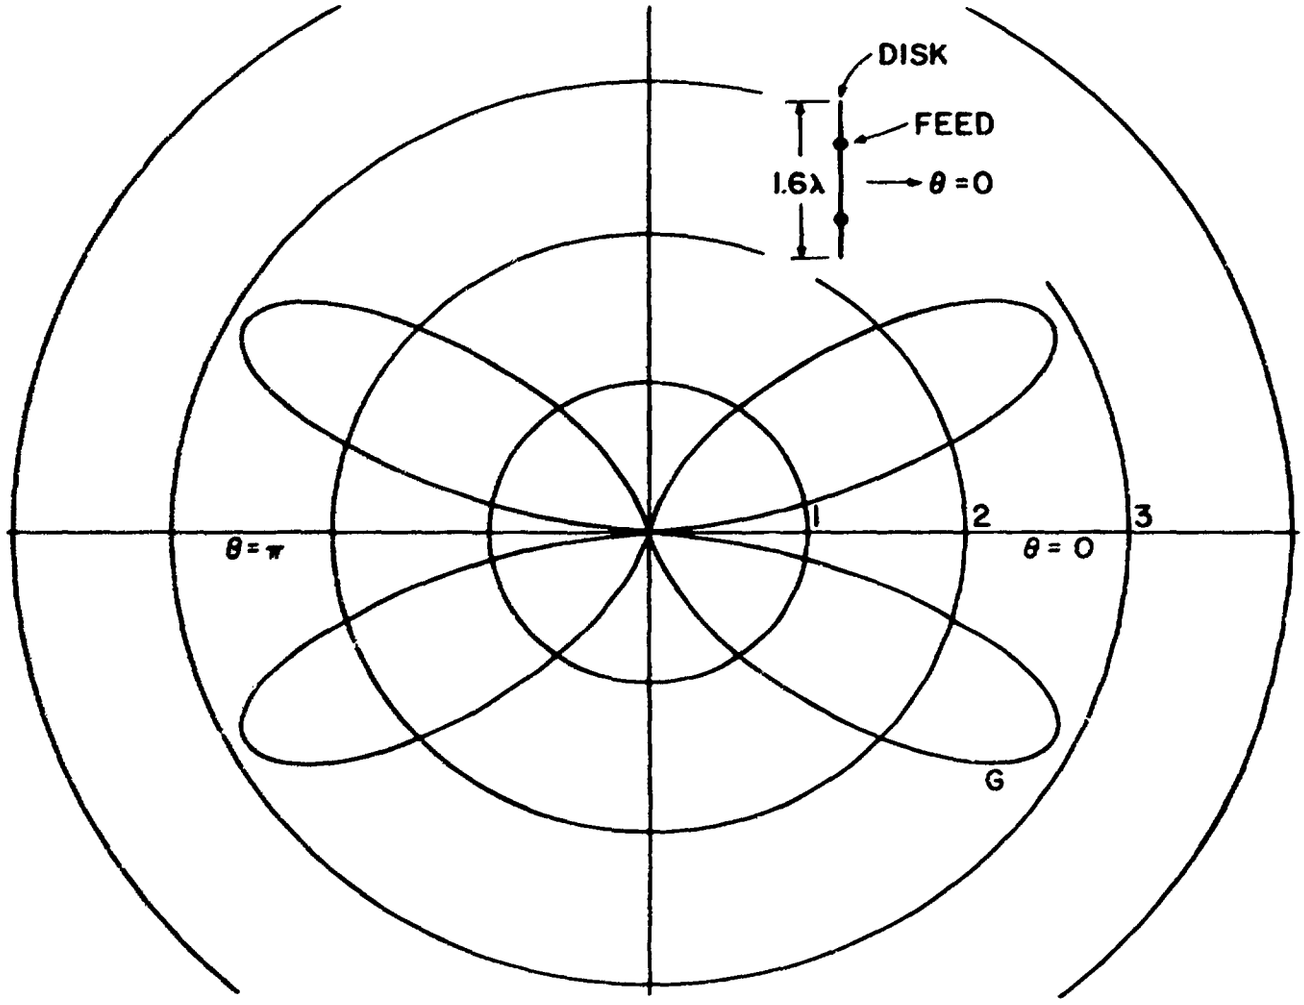

Figure 6. Power gain pattern for a conducting circular disk of 1.6λ diameter, excited by a voltage across a narrow slot of 0.8λ diameter.

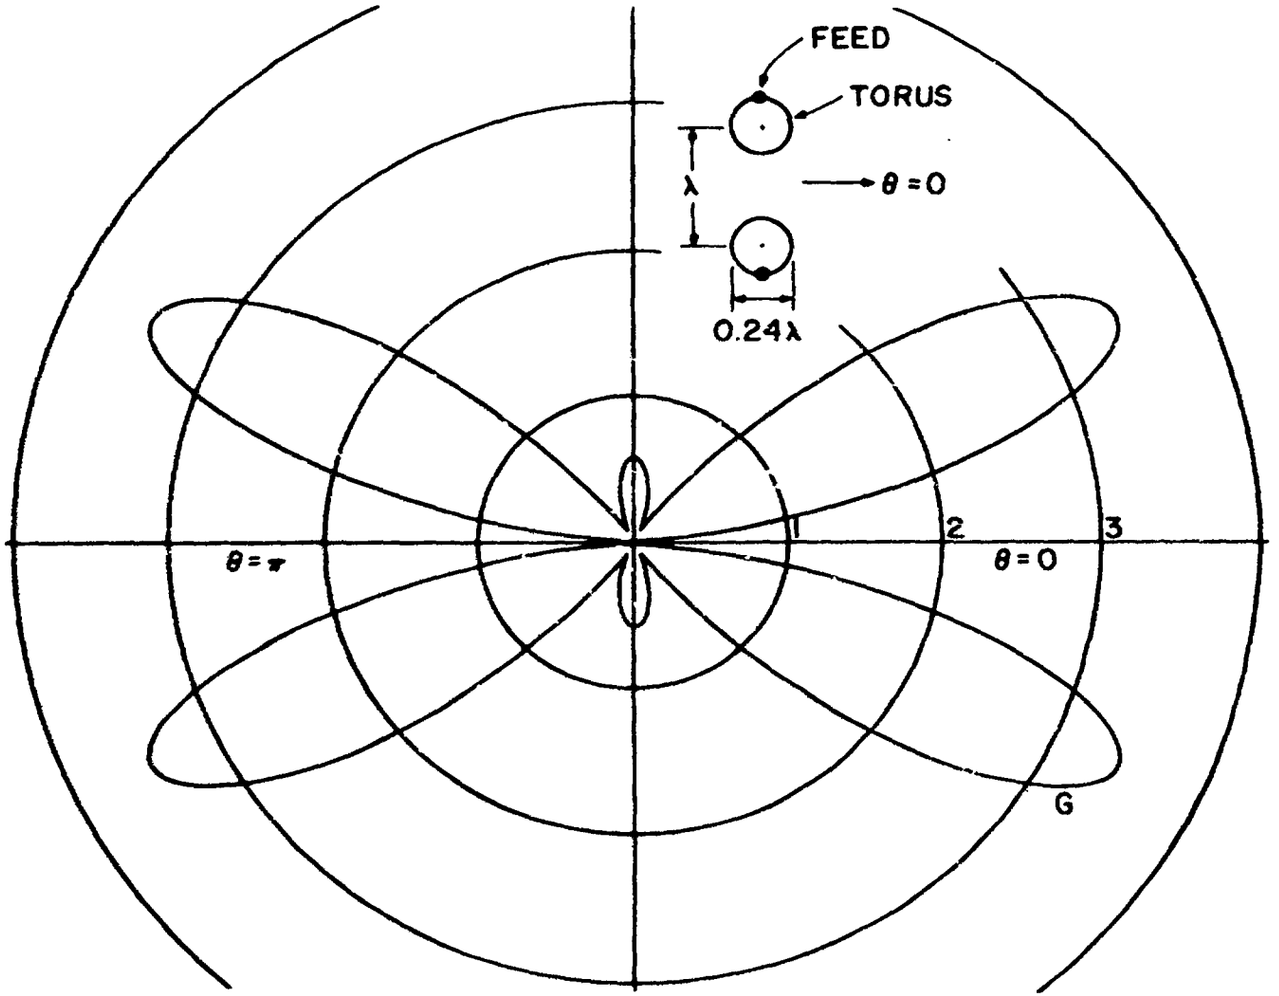

Figure 7. Power gain pattern for a conducting toroid of 1λ mean diameter and 0.24λ cross-sectional diameter, excited by a voltage across a narrow slot at the maximum diameter.

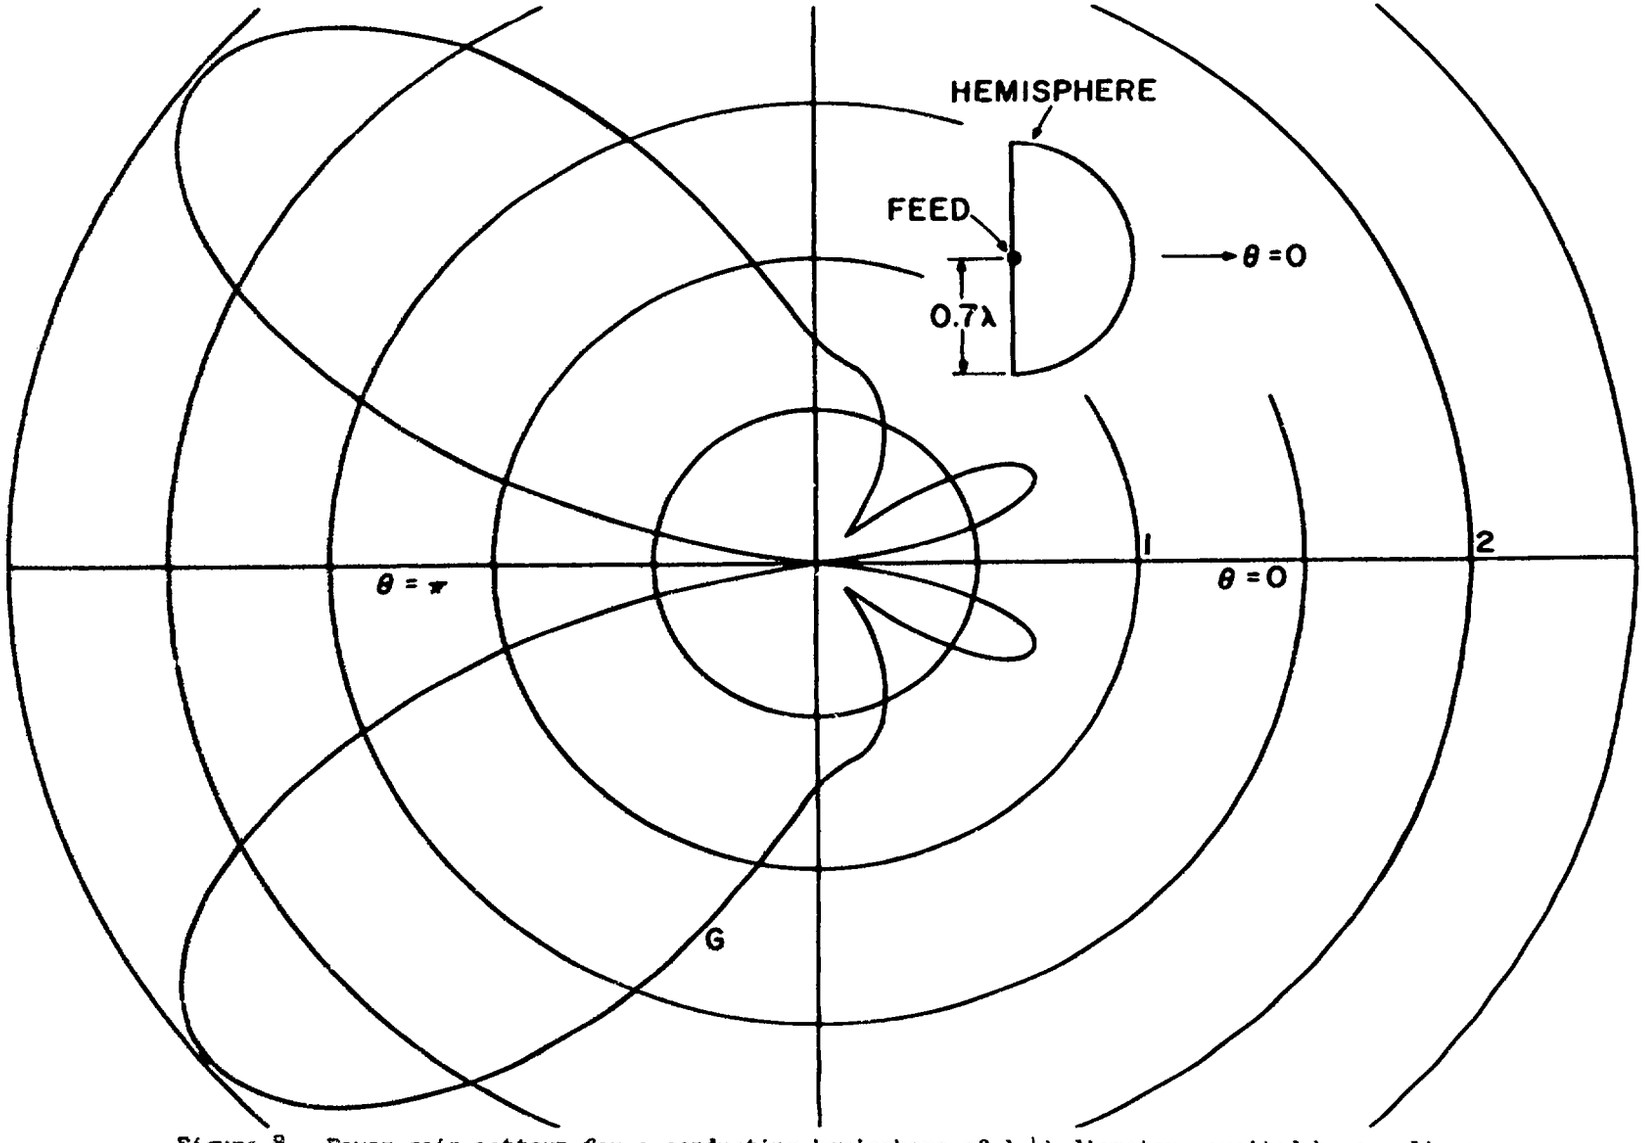

Figure 8. Power gain pattern for a conducting hemisphere of 1.4λ diameter, excited by a voltage across a small annular slot at the center of the flat face.

a narrow slot at a radius R = 0.4λ. Figure 7 is the power gain pattern for a toroid of mean radius 0.5λ and cross sectional radius r = 0.12λ, excited by a voltage across a narrow slot at the furthest point from the z axis. Figure 8 is the power gain pattern for a hemisphere of radius R = 0.7λ, excited by a voltage across a small annular slot at the center of the flat plate. This physically corresponds to excitation by an open-ended coaxial line. It is also equivalent to excitation by a small z-directed electric dipole at the center of the flat plate. Radiation from apertures in cone-spheres are shown in the previous report.[1] These computations are repeated in the computer print-out of Appendix C.

Figures 9 and 10 are examples of monostatic radar cross sections for bodies of revolution excited by plane waves of arbitrary direction of incidence. The curves of $\sigma^{\theta\theta}/\lambda^2$ are for θ-polarized incident waves, and the curves of $\sigma^{\phi\phi}/\lambda^2$ are for ϕ-polarized incident waves. There are no cross-polarized components of backscattered fields from bodies of revolution. Figure 9 shows the monostatic radar cross section of a disk of diameter D = 0.8λ. Figure 10 shows the monostatic radar cross section for a hemisphere of radius R = 0.7λ. The computer print-out of Appendix D gives the monostatic radar cross section for a cone-sphere, half cone angle 10°, sphere radius 0.2λ.

The computer print-out of Appendix D also shows the convergence of the pattern as more modes are included in the solution. Calling the modes which vary as $e^{\pm jn\phi}$ the n-th modes, for accurate far-field patterns one should include all modes for which

$$n \leq C_{max} + 1 \qquad (33)$$

where C_{max} = maximum body circumference in wavelengths. A justification of (33) can be made in terms of spherical mode theory. Those modes having n greater than C_{max} are cut-off, that is, are highly reactive and do not contribute materially to far-zone fields.

Similar convergence problems arise in aperture problems for which the excitation is not rotationally symmetric. To illustrate this, we have computed the power gain pattern for a cone-sphere excited by a voltage across a

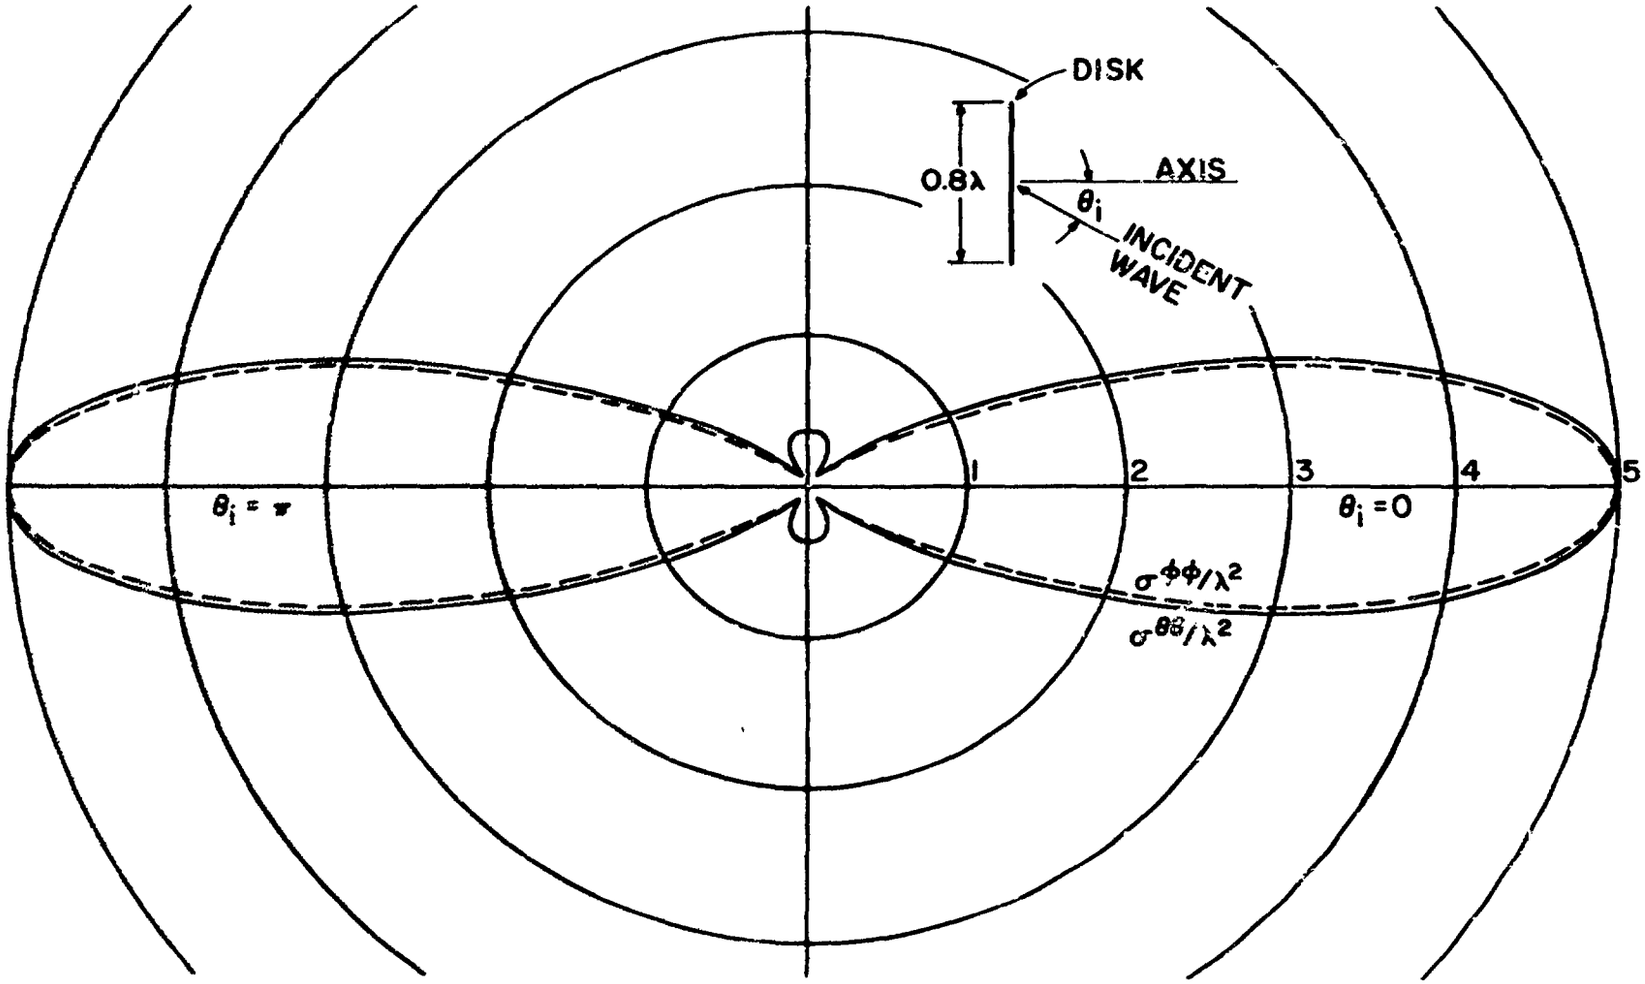

Figure 9. Monostatic radar cross section for a conducting disk of 0.8λ diameter, excited by a plane wave incident at an angle θ. The θ-polarized pattern is labeled $\sigma^{\theta\theta}$, and the ϕ-polarized pattern $\sigma^{\phi\phi}$.

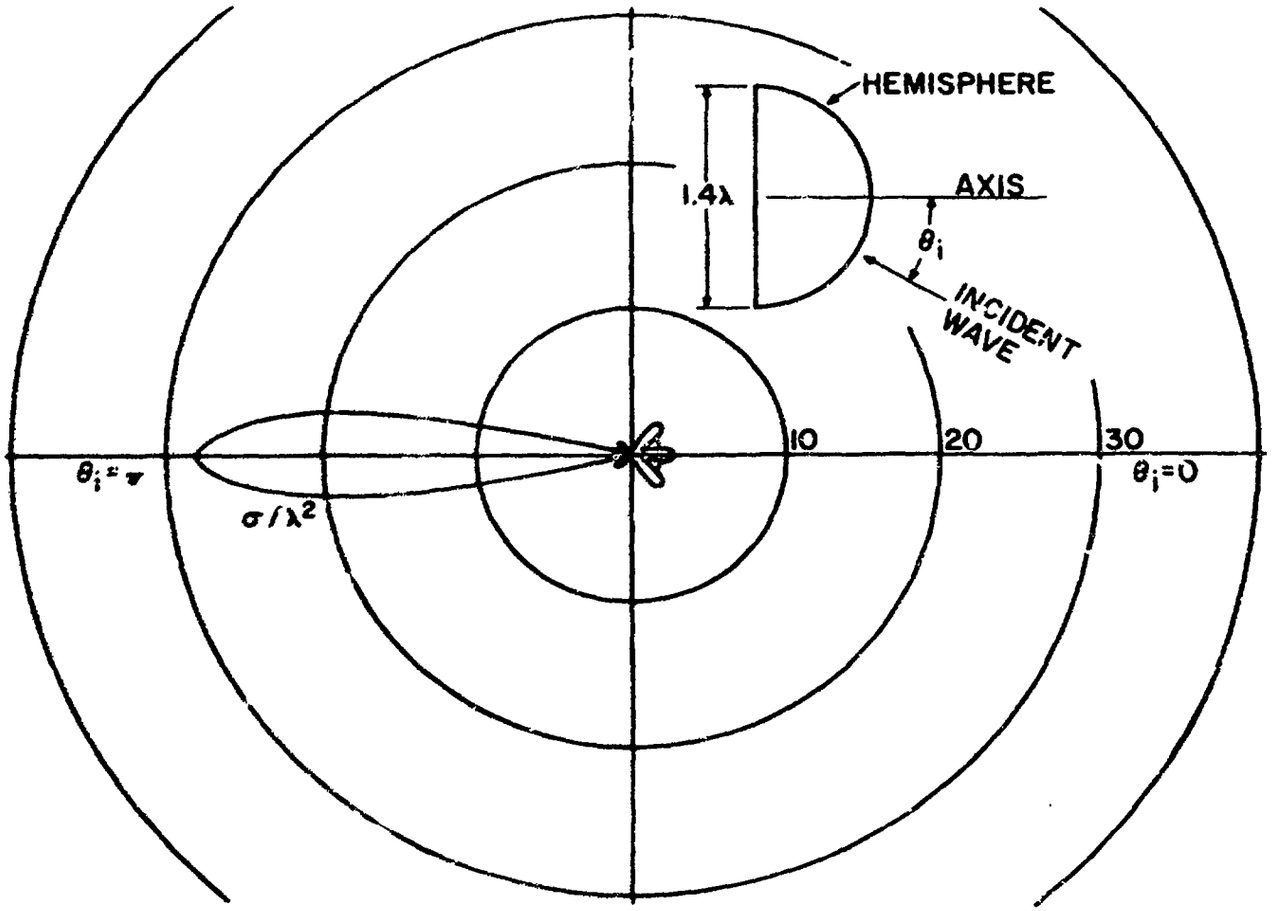

Figure 10. Monostatic radar cross section for a conducting hemisphere of 1.4λ diameter, excited by a plane wave incident at an angle θ. The θ-polarized and ϕ-polarized patterns are nearly the same.

slot at the cone-to-sphere junction, extending over a 90° angular sector of the body. Figure 11 shows how the power gain pattern converges as modes are added to the solution. All curves are normalized to the power radiated by the entire aperture, that is, to the sum of the modal powers. Note that criterion (33) is still a good indication of convergence.

Figure 12 illustrates a computation of monostatic radar cross section vs. frequency for a conical sector of a sphere. Our computations (x's) are compared to those by Schultz et al,[12] who used an eigenfunction expansion and nonfinal determination of coefficients. Also shown are an approximate solution of Keller and measurements by Keys. The accuracy of our computations is estimated to be better than can be read from the graph.

Computations for the cone-sphere, both as a loaded scatterer and as a loaded radiator, have been made. The dimensions of the cone-sphere and points of loading are pictured in Fig. 13. Computations were made for four types of loads as follows:

(A) Short circuit
(B) Open circuit
(C) Resonant load
(D) Matched load

For the scattering problem, these loads were applied one at a time to each of the four loading points. The plane-wave illumination was axially incident on either the point or the sphere. For the radiation problem, the excitation was taken at one of the four points, and one of the other points was loaded by one of the above loads. We have a complete set of these patterns for all permutations of the excitations and loads. Representative sets of scattering and radiation patterns are shown in Figs. 14 and 15 to illustrate the results.

IV. GENERALIZED NETWORK MATRICES

This program computes the [Z] and [Y] matrices for bodies of revolution. The theory is that of the previous report[1] modified to allow unequal segments of contour. The input data consists primarily of NP points specifying the contour plus the mode number. The output consists primarily of the

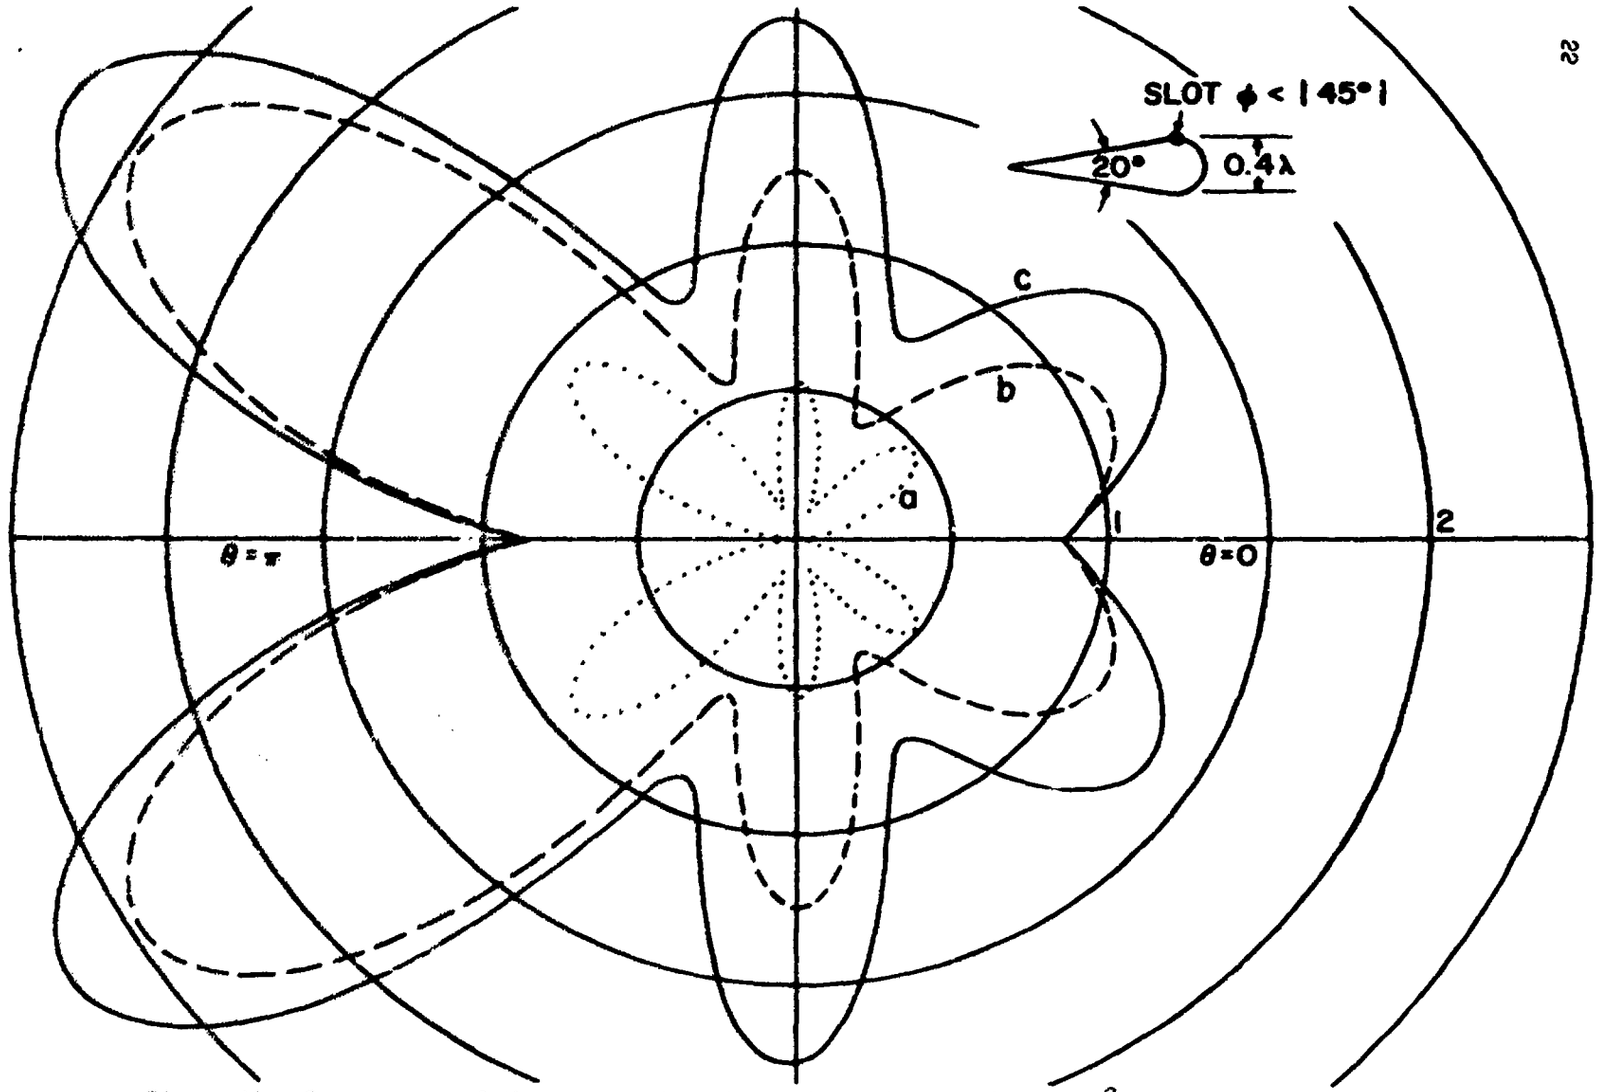

Figure 11. Convergence of the power gain pattern for radiation from a 90° slot in a conducting cone-sphere. Curve (a) is the n = 0 mode, curve (b) is the n = 0, ± 1 modes, curve (c) is the n = 0, ± 1, ± 2 modes. Addition of more modes did not materially change the pattern.

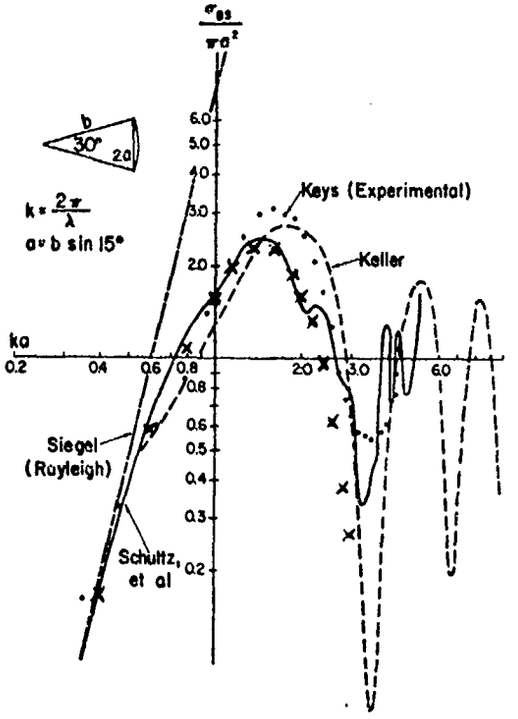

Figure 12. Monostatic radar cross section for a conical sector of a sphere, as computed and measured by various persons. Our computations are shown by x's.

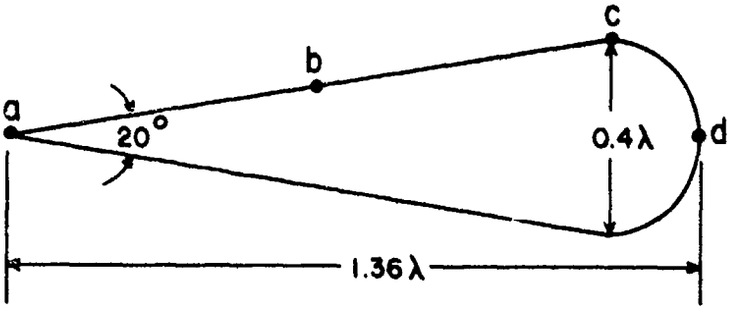

Figure 13. Conducting cone-sphere and points of loading.

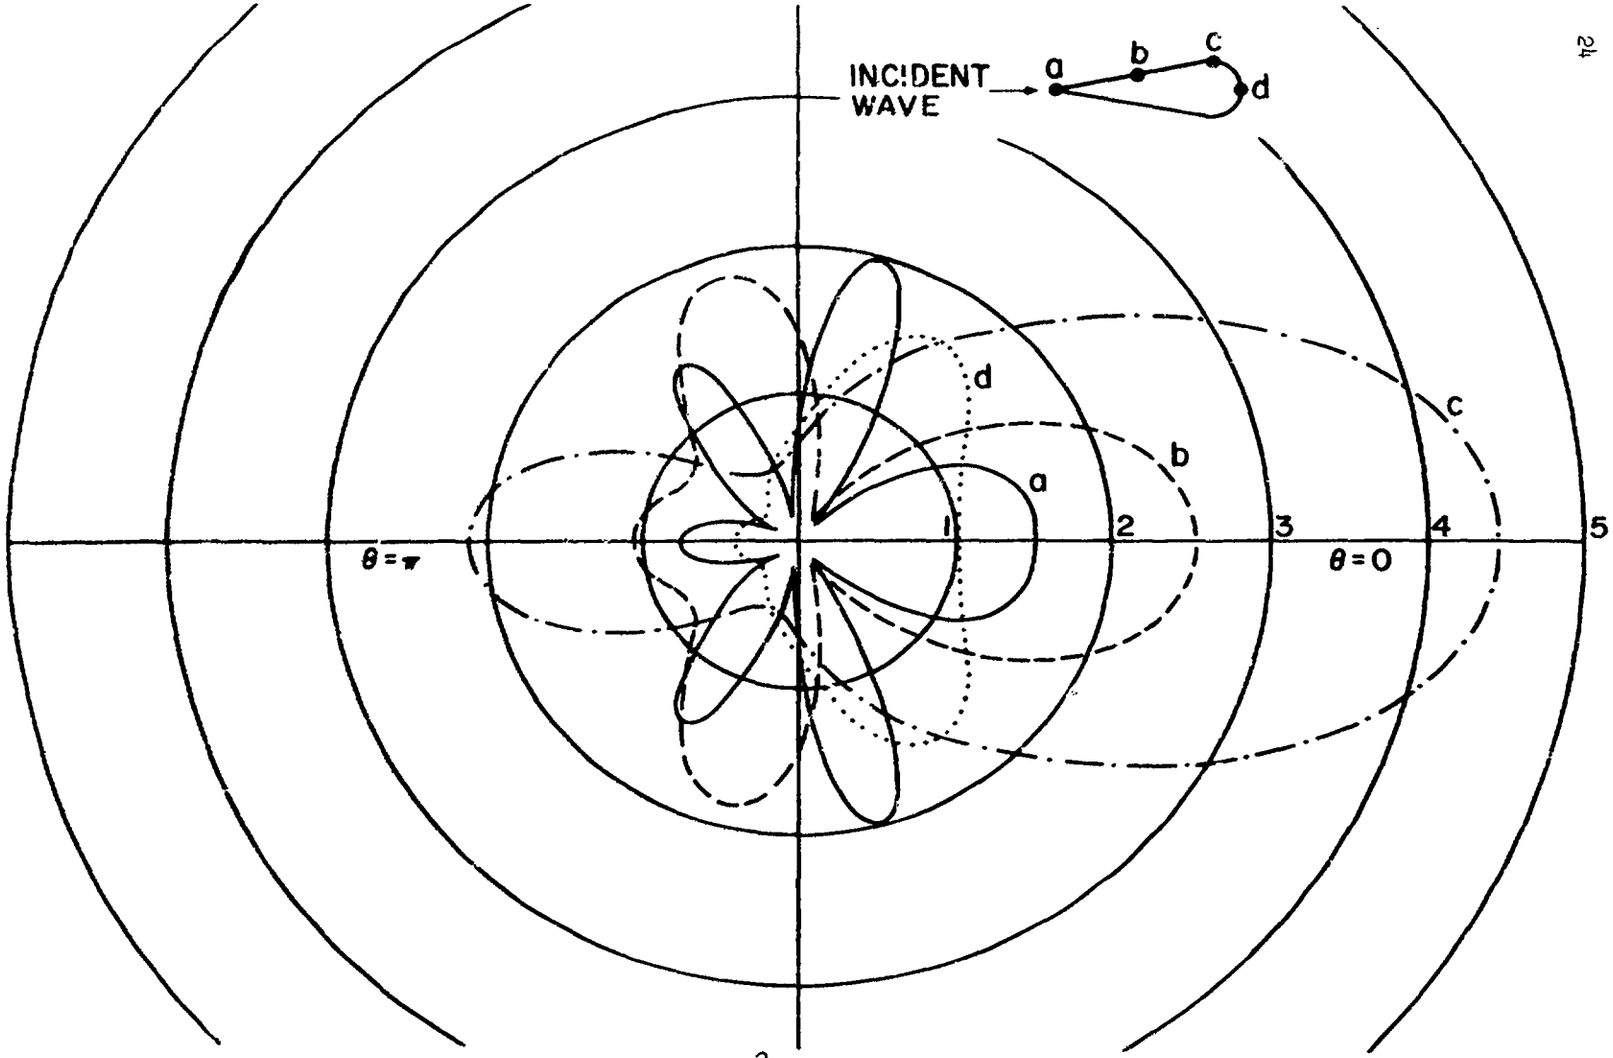

Figure 14. Bistatic scattering patterns (σ/λ^2 vs. θ) for a loaded cone-sphere. Loads are resonant bands at (a), (b), (c), or (d). The plane wave is axially incident on the tip, and the patterns are in the E plane. Cone angle is 20°, sphere diameter is 0.4λ. (Maximum σ/λ^2 for unloaded cone-sphere is 0.38.)

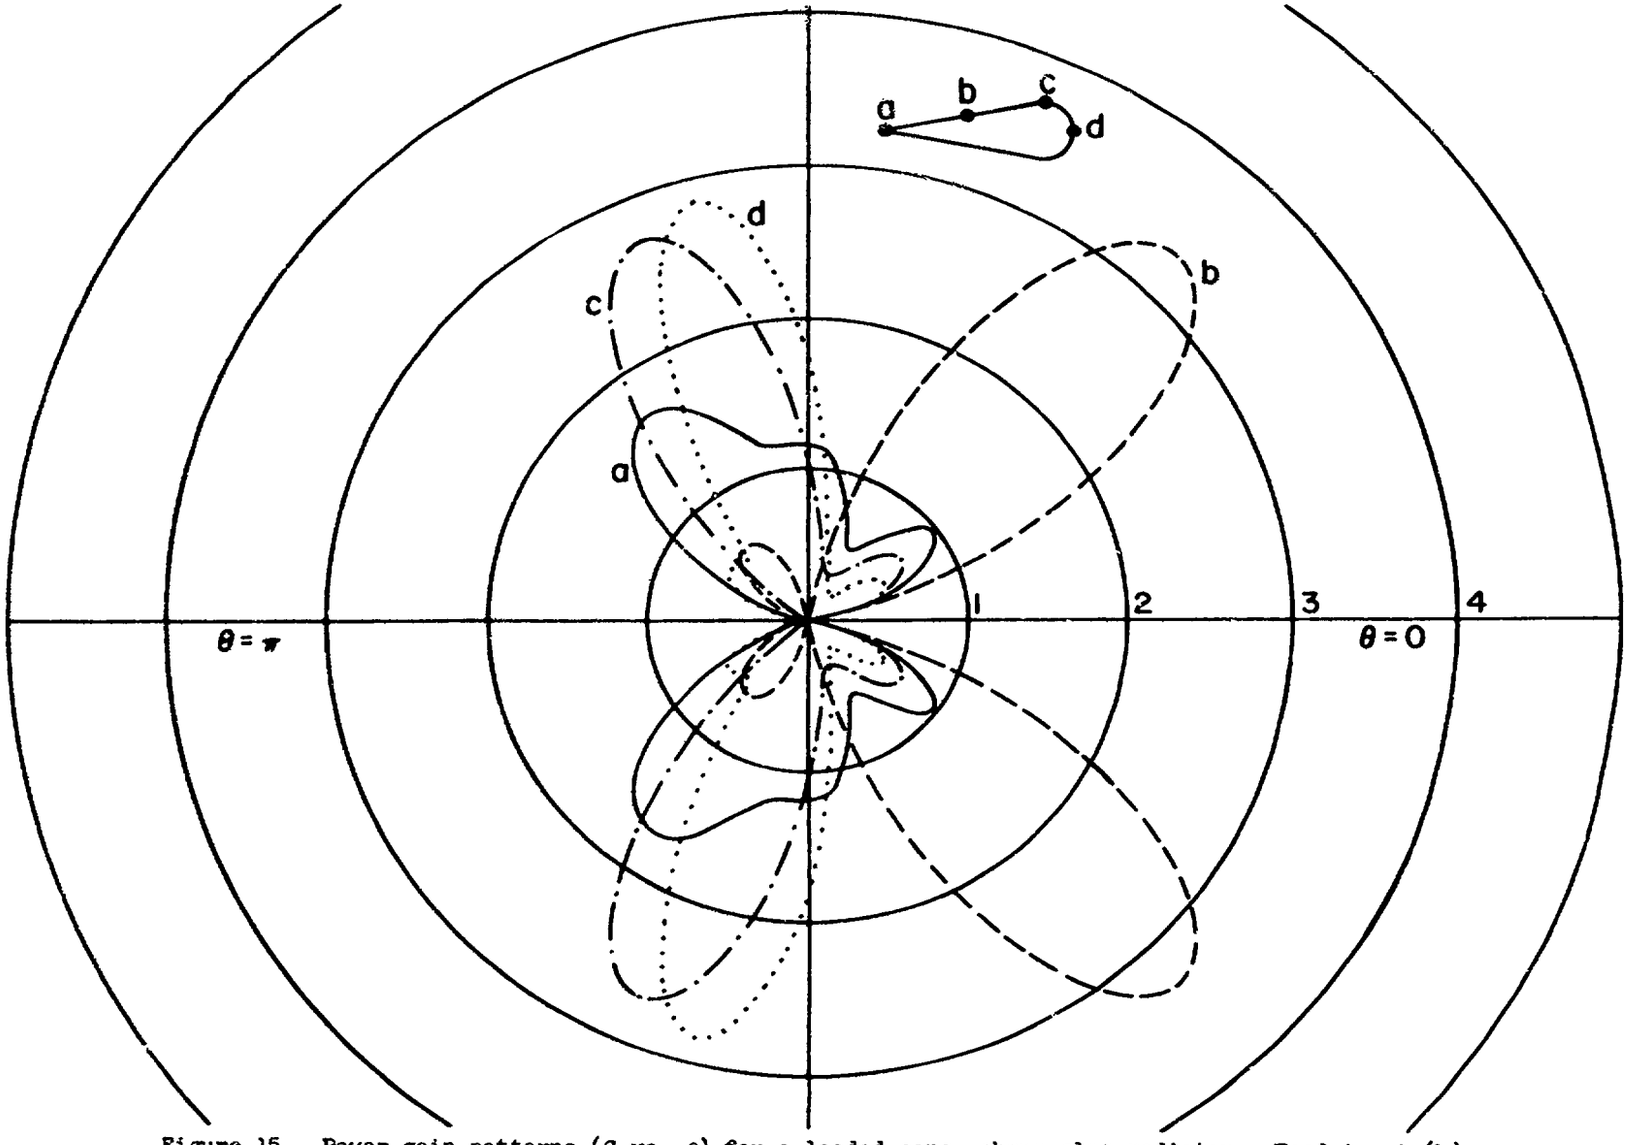

Figure 15. Power gain patterns (G vs. θ) for a loaded cone-sphere slot radiator. Feed is at (b). Loads are resonant bands at (a), (b), (c), or (d). Cone angle is 20°, sphere diameter is 0.4λ. There is no ϕ variation.

elements of the generalized admittance matrix for the particular mode. The program listing plus sample input-output data are given in Appendix A.

The subroutine LINEQ(LL,C) replaces the LL by LL matrix C by its inverse. C is a complex one-dimensional variable. The $(I,J)^{th}$ matrix element resides in C(I + (J-1) * LL). If LL > 58, the dimension of the variable LR must be increased to at least LL.

Punched card data is read early in the main program according to

```
   50 READ(1,51, END = 52) NN, NP, NPHI, BK
   51 FORMAT(3I3, E14.7)
      READ(1,53)(RH(I), I = 1, NP)
      READ(1,53)(ZH(I), I = 1, NP)
   53 FORMAT(10F8.4)
```

The excitation will have $e^{j(NN)\phi}$ dependence, NPHI has the same meaning as on page 55 of the previous report.[1] BK is the propagation constant $k = \omega\sqrt{\mu\epsilon}$. An odd number NP of points are taken from the generating curve of the body of revolution. RH(I) and ZH(I) are respectively the distance ρ from the axis (z axis) of the body of revolution and the corresponding z coordinate. RH(I) may be zero only when I = 1 or I = NP. If the generating curve closes upon itself, care must be taken to make the coordinates at I = 1 identical to those at I = NP. The data is printed just after it is read.

If the first and NP^{th} data points are the same, the second and third data points are overlapped into the NP + 1 and NP + 2 position and NP is increased by two before going to do loop 57 which interpolates to find the distance DH(I) between the I^{th} and $(I + 1)^{th}$ data points, the radius ρ midway between the I^{th} and $(I + 1)^{th}$ data points, the corresponding z coordinate ZS(I), and the sine SV(I) and cosine CV(I) of the angle between the z axis and the straight line from the I^{th} to the $(I + 1)^{th}$ data points. Next, a few constants are entered among which PI is π and ETA is the intrinsic impedance $\eta = 376.707$ taken from the second edition of Smythe.[13] The third edition of Smythe gives $\eta = 376.730$. DO loop 117 computes the t coordinate (arc length along the generating curve) TJ(I) of the peak of the I^{th} triangular expansion function. TJ is printed. DO loop 10 calculates

$$CSM(K+(I-NN+1)*NPHI) = \frac{PI}{NPHI} * \cos\left[\quad I \quad * \frac{PI*(K-.5)}{NPHI}\right] \text{ for } K = 1,2,\ldots NPHI$$

and I = NN-1, NN, NN+1.

DO loop 16 calculates

$$\frac{1}{DH(J)} \int dt \int_0^{\pi} d\phi \, \frac{e^{-jkR}}{kR} \cos n\phi \qquad (34)$$

The t integration is over the portion (assumed to be a straight line) of the generating curve between the J^{th} and $(J+1)^{th}$ data points. ϕ is the angle swept when the generating curve is revolved about the z axis. R is the distance between some field coordinate (t', $\phi' = 0$) and the source coordinates (t, ϕ). The expression (34) is proportional to the scalar potential at (t', 0) coming from a $\frac{\cos n\phi}{\rho}$ charge density on the lateral surface of the frustum of a cone. The index J of do loop 16 indicates that the source coordinate t is between the J^{th} and $(J+1)^{th}$ data points. The index I of do loop 17 indicates that the field coordinate t' is midway between the I^{th} and $(I+1)^{th}$ data points. Except when the field point lies on the surface charge, the surface charge is approximated by line charges at $\phi = \frac{(K-.5)*PI}{NPHI}$, K = 1,2,...NPHI. When the field point lies on the surface charge, the surface charge $\frac{\cos n\phi}{\rho}$ is approximated by cos (.5*PI/NPHI)/R(I) when $0 \leq \phi \leq \frac{PI}{NPHI}$, but for the region $\frac{\pi}{NPHI} < \phi \leq \pi$ the line charges at $\phi = \frac{(k-.5)*PI}{NPHI}$, K = 2,3,...NPHI are used. Do loop 5 stores the results of the t integrations at $\phi = \frac{(K-.5)*PI}{NPHI}$, K = 1,2,$\cdots$NPHI in GS. Do loop 13 multiplies the GS(K) by $\frac{PI}{NPHI} * \cos\left(n*\frac{(K-.5)*PI}{NPHI}\right)$ and sums them over K to obtain expression (34) stored in G. Do loop 68 obtains n = NN-1, NN, and NN+1. The location G(I + (J-1)*(NP-1) + (NP-1) * (NP-1) *(n-NN+1)) corresponds to field point I, source region J and mode n. If the generating curve closes upon itself, the present NP is two more than the original NP of the input data.

The impedance matrix Z will be the same as that of equation (45) of the previous report[1] except that the previously defined G_n's will be used and the T_p and T'_p are modified. Also, since the new G_n's are divided by k to make them insensitive to the absolute size of the body of revolution, the

new Z's must be multiplied by k. Because of possible unequal spacing of data points the 8 numbers T_p and T_p' were stored separately for each triangular expansion function. In do loop 74, the index J refers to the J^{th} triangular function while the numbers T_p and T_p' are stored in T and TP respectively. The J^{th} triangular function is approximated by 4 pulses of base lengths DH(I + 2 *(J-1)), I = 1,2,3,4. The derivative of the J^{th} triangular function is just a pulse doublet. Denoting base lengths by Δ_1, Δ_2, Δ_3, and Δ_4,

$$
\begin{aligned}
T(1 + 4*(J-1)) &= \frac{\Delta_1^2}{2*(\Delta_1+\Delta_2)} \\
T(2 + 4*(J-1)) &= \frac{(\Delta_1 + .5*\Delta_2)*\Delta_2}{\Delta_1 + \Delta_2} \\
TP(1 + 4*(J-1)) &= \frac{\Delta_1}{\Delta_1 + \Delta_2} \\
TP(2 + 4*(J-1)) &= \frac{\Delta_2}{\Delta_1 + \Delta_2}
\end{aligned}
\qquad (35)
$$

Similar expressions involving Δ_3 and Δ_4 are used to treat the trailing edge of the triangular function. Expressions (35) are functional values (T for the triangle and TP for the derivative of the triangle) weighted by the base length in question. The base length weighting is necessary because the G_n's have a factor $\frac{1}{DH(J)} = \frac{1}{\Delta_j}$ which must be offset. Also, the factor Δ_j is necessary for the field integration. For the field integral, the triangular function and its derivative are each approximated by four delta functions.

Unless the generating curve closes upon itself, there will be no peak of triangular function at the starting point and end point. The expansion function which is actually a triangular function over radius ρ will reduce to a constant at a starting point or end point on the z axis. However, if the starting point or end point is not on the z axis, the expansion functions reduce to zero there. In problems involving, perhaps, a conducting disk, the electric current normal to the rim goes to zero as the square root of the distance from the rim and the current parallel to the rim becomes large as one

over the square root of the distance from the rim, at least when an incident plane wave propagates perpendicular to the plane of the disk. The triangular functions used to expand the ϕ directed current were modified near the extremities of the generating curve where no overlapping occurs remote from the z axis. The triangular function (associated with the ϕ directed current) nearest such an extremity was modified by increasing its value at the extremity from zero to two. The logic from statements 115 to 116 performs this modification. Whereas the triangular functions associated with the t directed current were stored in T, the functions associated with the ϕ directed current are assigned TR.

Using G_n, T, TP, and TR the impedance matrix is calculated inside do loop 30. The calculation of the present impedance elements is very similar to a previous calculation using equation (45) of the previous report.[1]

Statement 81 CALL LINEQ (NM2, Z) inverts the impedance matrix stored in Z to obtain the admittance matrix. The admittance matrix is printed inside do loop 93. If superscripts $t\phi$ are replaced by rs and if r = 0 denotes t, r = 1 denotes ϕ and similarly for s, then $(Z_n^{rs})_{ij}$, i = 1,2,$\cdots$N-1 is given by the $[J + r * (N-1) + s * 2 * (N-1)]^{th}$ execution of write statement 96. Here, N-1 is the number (either $\frac{NP-3}{2}$ or $\frac{NP-1}{2}$) of triangular functions. Immediately following statement 81, the admittance matrix of the array Z is recorded on a direct access device by

```
WRITE(6) (Z(I), I = 1, NZ)
```

If no direct access device is available, statements should be added to either punch the admittance matrix on cards or store it on tape. At the end of the program, execution is transferred back to read statement 50. If there is another set of data, it is processed. If not, execution terminates.

The dimension statements in the main program will not accommodate NPHI larger than 40 nor NP larger than 41 if the generating curve closes on itself. If the generating curve does not close on itself, NP may be as large as 43. Assuming that the generating curve might close on itself, minimum dimensions are:

```
COMPLEX Z((NP-1)*(NP-1)), GS(NPHI), G(3*(NP+1)*(NP+1))
DIMENSION RH(NP+2), ZH(NP+2), DH(NP+2), TJ((NP-1)/2)
DIMENSION SV(NP+1), CV(NP+1), ZS(NP+1), R(NP+1),
          ANG(NPHI), AC(NPHI), CSM(3*NPHI)
DIMENSION TP(2*(NP-1)), T(2*(NP-1)), TR(2*(NP-1))
```

The NP referred to above is the original NP of the input data.

V. PLANE-WAVE SCATTERING, AXIAL INCIDENCE

This program computes the current on a conducting body of revolution and scattering patterns for excitation by a plane wave axially incident on the body. The input consists primarily of NP points defining the body contour, plus the [Y] matrix for the n = 1 mode. The output consists primarily of the current on the body, the scattered far-zone field, and the bistatic radar cross section. Printer plot routines are included to graph both the current and the radar cross sections. The program listing plus sample input-output data are given in Appendix B.

Subroutine PLANE(VVR, THR, NT) provides the measurement matrix elements of equations (77) and (81) of the report.[1] NT angles θ_r (in radians) appear as input in THR. Other input appears in the common statement. U is the complex constant (0.,1.), R, ZS, SV and CV are respectively the radius ρ, the z coordinate, and the sine and cosine of the angle between the direction of the generating curve and the z axis. R(I), ZS(I), SV(I) and CV(I) are evaluated midway between the I^{th} and $(I+1)^{th}$ data points RH and ZH by drawing a straight line between them. BK is the propagation constant, there are (NP-1) R's, the excitation has $e^{j(NN)\phi}$ dependence, and T and TR are the previously computed weighted samples of the triangular functions for both the t and ϕ directed electric currents. When execution returns to the main program, the $(R_n)_i$ of equation (77) or (81) of the report[1] will be stored in VVR(I + (K-1)*NM + (L-1)*4*NM) where K = 1,2,3,4 denotes respectively $(R_n^{t\theta})_i$, $(R_n^{\phi\theta})_i$, $(R_n^{t\phi})_i$ and $(R_n^{\phi\phi})_i$. As defined in the subprogram, NM is the number $\frac{NP-2}{2}$ of the triangular functions and L denotes the L^{th} of the angles θ_r.

In the subroutine PLANE, do loop 153 puts J! in FK(J+1). Do loop 156 sweeps the NT angles θ_r. Do loop 302 computes the required Bessel functions according to $J_n(x) = \sum_K \frac{(-1)^K (\frac{x}{2})^{n+2K}}{K!\,(n+K)!}$. If the series for $J_n(x)$ does not converge readily, do loop 155 may be satisfied in which case error stop 155 is reached. When $\rho = R(J)$, $J_{NN+K}(k_\rho \sin \theta_r)$ will be stored in BJ(J + (K+1)*(NP-1)) for K = -1,0,1. To avoid direct computation of a Bessel function of negative order when NN = 0, $J_{-1}(x)$ is obtained from $J_1(x)$ in do loop 309. With ρf_i being represented by either T or TR, the t integration of equations (77) and (81) of the report[1] is simulated in do loop 301. The ρf_i triangular function is approximated by four delta functions.

If NP (either the original NP of the data or 2 plus it if the generating curve overlaps) is larger than 43, the dimension of some of the variables in PLANE must be increased. These variables and their dimensions are:

```
COMMON R(NP-1), ZS(NP-1), SV(NP-1), CV(NP-1),
       T(2*(NP-3)),TR(2*(NP-3))
DIMENSION BJ(3*(NP-1))
```

The common statement in the subroutine PLANE should be identical to that in the main program. In the unlikely case that the mode number NN is larger than 17, the dimension of FK must be increased to NN+3. Since the arguments VVR and THR are only dummy variables, their present dimension of 1 is always sufficient.

The subroutine REORD(K1, K3, L) rearranges the first L elements of K3 in descending order. Also, the first L elements of K1 are rearranged so as to maintain the original correspondence between the elements of K3 and those of K1.

Punched card data is read in early in the main program according to

```
   50  READ(1,51, END = 52) NN, NP, NT, BK
   51  FORMAT(3I3, E14.7)
       READ(1,53)(RH(I), I = 1,NP)
       READ(1,53)(ZH(I), I = 1,NP)
   53  FORMAT(10F8.4)
```

All the input variables except NT are the same as the variables of the previous program. The receiver angles θ_r are given by

$$(\theta_r)_i = \frac{\pi(i-1)}{NT-1} \ , \ i = 1,2,\cdots NT$$

The punched card data is printed out immediately after it is read in.

Statement 126 checks to see whether the first and last points on the generating curve are identical. If they are identical, the variable KL is set equal to 0 and RH and ZH are expanded by overlapping the second and third points on the generating curve. In this way, an expansion function centered about the last original data point is obtained. If the first and last original data points are not identical, KL is 1 and execution proceeds to statement 58 in which case there are no expansion functions centered about the first and last data points. The logic between statements 58 and 78 prepares input data for the subroutine PLANE. Statement 85 inserts the receiver voltage matrices into VVR. Statement 127 inputs the admittance matrix appearing in (17) of the report.[1] This admittance matrix will have been generated by the previous computer program.

Nearly all the statements following statement 127 are enclosed in do loop 108. When INC = 1, the electric field of the incident plane wave is $\mu_x e^{-jkz}$ and when INC = 2 it is $-\mu_x e^{jkz}$. The I column vector of equation (17) of the report is computed in do loop 2 and stored in TI. The inner do loop 3 uses transmitter voltage matrices obtained from the last ($\theta_r = \pi$, INC = 1) and first ($\theta_r = 0$, INC = 2) receiver voltage matrices. Equation (82) of the report[1] and the fact that $R_n^{t\theta}$ is even in n and $R_n^{\phi\theta}$ is odd in n are used to relate the transmitter voltage matrices to the receiver voltage matrices. Do loops 7 and 8 compute TJ(J), the arc length which locates the center point of the J^{th} expansion function along the generating curve. The total length of the generating curve is normalized to 10. Do loop 9 performs the matrix multiplication indicated in equation (65) of the report.[1] The measurement is stored in E1 and E2 corresponding to the θ and ϕ receiver polarizations. In do loop 11, E1 and E2 are normalized so that the quantity σ/λ^2 associated with each one is the square

of its magnitude. The phase of E1 is set equal to zero in the backscattering direction which is $\theta_r = \pi$ for the e^{-jkz} incidence and $\theta_r = 0$ for the e^{+jkz} incidence.

Do loop 128 divides the expansion function coefficients by ρ to obtain the current. A multiplication by 2 or 2j converts from the exponential $e^{j\phi}$ to cos ϕ or sin ϕ. The factor η is necessary to normalize the current to the incident magnetic intensity $\underline{H}^i$. Do loop 129 averages the ϕ directed current J_ϕ according to

$$\frac{J_\phi(i-1) + 2J_\phi(i) + J_\phi(i+1)}{4}$$

The averaging was deemed necessary to attenuate extraneous oscillations in J_ϕ. If the generating curve does not close upon itself, the first and last J_ϕ are not averaged. Do loop 4 prints the arc length and real and imaginary parts and magnitude of the t and ϕ directed current. For an incident magnetic intensity $\underline{H}^i = \underline{u}_y e^{-jkz}$ (INC = 1) or $\underline{H}^i = \underline{u}_y e^{jkz}$ (INC = 2), the current sinor $\underline{J}$ is given in terms of the printed output JT and Jϕ by

$$\underline{J} = \underline{u}_t JT \cos\phi + \underline{u}_\phi J\phi \sin\phi$$

Do loop 12 prints the scattering patterns as functions of θ_r. SIG Xθ is σ/λ^2 in the E plane and SIG Xϕ is σ/λ^2 in the H plane. LSIG Xθ is $\log_{10} \sigma/\lambda^2$ in the E plane and LSIG Xϕ is $\log_{10} \sigma/\lambda^2$ in the H plane. SIG Xθ and SIG Xϕ are respectively the magnitudes squared of SXθ and SXϕ. The phase of SXθ is taken to be zero in the backscattering direction. The magnitudes (MAG) and phase (ANG) of SXθ and SXϕ are also tabulated. The scattered electric field will be proportional to

$$\underline{u}_\theta (SX\theta) \cos\phi + \underline{u}_\phi (SX\phi) \sin\phi$$

All the statements following do loop 12 are devoted to obtaining plots of the previously tabulated quantities MAG JT, MAG Jϕ, SIG Xθ, and SIG Xϕ. Do loop 13 scales the current for plotting. KJ is the t directed current

and K4 is the ϕ directed current. K3 has been assigned the abscissa K1 and K4 the abscissa K2. After execution of statements 14 and 15, K3(J) will be the J^{th} largest K3 and K1(J) its abscissa. The quantities K3 and K4 with abscissas K1 and K2 are plotted by do loop 20. Entering do loop 20, K5 = 1. One line is printed for each J. If K3(K5) is greater than or equal to (51-J), an X is written after K1(K5) blanks and K5 is incremented by one. If K3(K5) is still greater than or equal to (51-J), another X is written after K1(K5) blanks and K5 is incremented. The process continues until K3(K5) is less than (51-J) in which case statement 20 is reached. Similar action is associated with K4 and K2. If K3(NM) is larger than or equal to zero, K3(NM+1) will be observed, but K3(NM+1) has been set equal to -1 immediately after do loop 14.

The patterns SIG Xθ and SIG Xϕ are plotted in a similar fashion. Actually, the logarithms of SIG Xθ and SIG Xϕ are plotted but the scale is graduated in terms of SIG Xθ and SIG Xϕ to simulate semi-log paper. Do loop 80 generates the abscissas K1 and K2 and ordinates K3 and K4. Statements 16 and 17 arrange K3 and K4 in descending order. Do loop 87 plots SIG Xθ and SIG Xϕ as X's and 0's respectively. After do loop 108 is satisfied, execution goes back to the read statement 50. If another set of input data is encountered, execution traverses the program again. If not, execution stops.

Let NP be either the original NP of the data if the generating curve does not close upon itself or 2 plus the original NP of the data if the generating curve closes upon itself. When NP > 43 or NT > 73, some variables require larger dimensions. These variables are listed along with their minimum dimensions.

```
COMPLEX Y(4*NM*NM), VVR(4*NT*NM), TI(2*NM),
       E3(NM), E1(NT), E2(NT)
COMMON R(NP-1), ZS(NP-1), SV(NP-1), CV(NP-1), T(4*NM), TR(4*NM)
DIMENSION RH(NP), ZH(NP), DH(NP-1), TJ(NM), THR(NT)
DIMENSION K1(NM), K1(NT), K2(NM), K2(NT), K3(NM), K3(NT), K4(NM), K4(NT)
```

The variables K1, K2, K3 and K4 must be dimensioned at least as large as the larger of NM and NT. Here, as in the main program, NM = $\frac{NP-3}{2}$.

VI. APERTURE RADIATION, ROTATIONAL SYMMETRY

This program computes the current on a conducting body of revolution excited by one or more rotationally symmetric apertures. It is assumed that the tangential electric field is known over the apertures. The input consists primarily of NP points defining the body contour, the [Y] matrix for the n = 0 mode, plus tangential E at the NP points on S. The output consists primarily of the current on the body, the radiation field, and the normalized power gain patterns. Printer plot routines are included to graph both the current and the power gain patterns. The program listing plus sample input-output data are given in Appendix C.

The program is similar to the one concerning scattering for axially incident plane waves except that the excitation voltage matrix is determined by input data instead of by an incident plane wave. Also, a gain instead of a scattering cross section is obtained from the measurement. (Equation (69) of the report.[1])

The subroutine PLANE provides the measurement matrix elements of equations (77) and (81) of the report[1] for the special case n = 0. This subroutine PLANE is similar to the subroutine of the same name used in the program concerning scattering for axially incident plane waves. For the case n = 0, $R^{\phi\theta}$ and $R^{\phi\phi}$ may be dispensed with since they are zero.

The subroutine REORD is exactly the same as the one of the same name appearing in the program concerning scattering for axially incident plane waves.

Punched card data is read early in the main program according to

```
   50  READ(1,51,END = 52) KK, NP, NT, BK
   51  FORMAT(3I3, E14.7)
       READ(1,53)(RH(I), I = 1, NP)
       READ(1,53)(ZH(I), I = 1, NP)
```

```
 53  FORMAT(10F8.4)
     IF(KK.EQ.2) GO TO 40
     READ(1,68)(E1(I), I = 1,NP)
168  FORMAT(7E11.4)
     IF(KK.EQ.1) GO TO 41
 40  READ(1,168)(E2(I),I = 1, NP)
 41  KL = 1
```

KK = 1 if the aperture electric field has only a t component.
KK = 2 if the aperture electric field has only a ϕ component.
KK = 3 if the aperture electric field has both t and ϕ components. NP points define the generating curve of the body of revolution. The first point and the NP^{th} point mark the extremities of the generating curve. NP must be odd. The gain pattern will be observed at NT angles θ_r. In degrees,

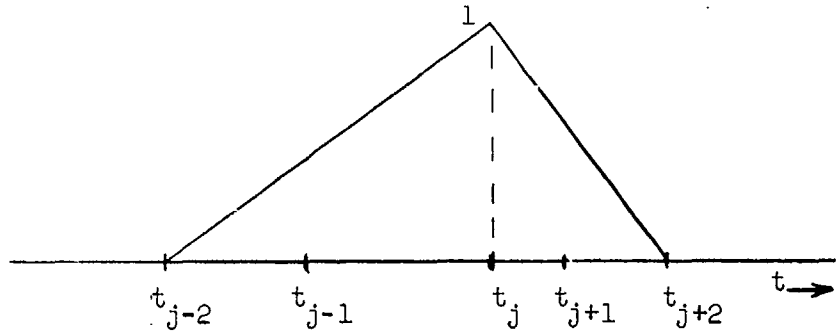
$$\theta_r = \frac{180(I-1)}{NT-1} \quad , \quad I = 1,2,\cdots NT.$$

BK is the propagation constant $k = \omega\sqrt{\mu\epsilon}$. RH(I) and ZH(I) are respectively the cylindrical coordinate radius ρ and axial distance z at data point I of the generating curve. E1 and E2 are complex. If KK $\neq$ 2, E1(I) is the t component of the axially symmetric aperture electric field at point I on the generating curve. All the E1's except E1(J) being zero represents an aperture field $\frac{E1(J)}{2}$ between the $(J-1)^{th}$ and $(J+1)^{th}$ points or between the J^{th} and $(J+1)^{th}$ points if J = 1 or between the $(J-1)^{th}$ and J^{th} points if J = NP. If RH(1) = RH(NP) $\neq$ 0 and ZH(1) = ZH(NP), an E1(1) must be accompanied by an identical E1(NP). If KK $\neq$ 1, E2(I) represents a ϕ directed aperture field in exactly the same way as E1(I) represented a t directed aperture field. If KK = 3, both E1 and E2 occur simultaneously. The punched card data is printed out soon after it is read.

Statement 126 sets KL = 0, overlaps two of the data points and adds 2 to NP if the generating curve closes upon itself. Do loop 57 draws a straight line between the $(I+1)^{th}$ and I^{th} data points to obtain DH(I), R(I), ZS(I),

SV(I), and CV(I), the increment of arc length, the cylindrical coordinate radius, the axial distance, and the sine and cosine of the angle between t and the z axis, all evaluated midway between the $(I+1)^{th}$ and I^{th} data points. Do loop 1 stores the NT angles θ_r in THR.

The triangle functions (equation 31 of the report[1]) are modified slightly if the data points on the generating curve are not exactly equally spaced.



$T_i(t)$ for $i = (\frac{j-1}{2})$

For J odd, the $(\frac{J-1}{2})^{th}$ modified function is given by

$$T_i(t) = \begin{cases} 1 + \dfrac{t-t_j}{t_j-t_{j-2}} & t_{j-2} \le t \le t_j \\ 1 - \dfrac{t-t_j}{t_{j+2}-t_j} & t_j \le t \le t_{j+2} \\ 0 & \text{all other t .} \end{cases}$$

where $i = \frac{(j-1)}{2}$.

The subscript j on t indicates the J^{th} data point. For J odd, this $(\frac{J-1}{2})^{th}$ function is characterized by 4 numbers T(2*J-6+I), I = 1,2,3,4. Coming out of do loop 74, T(2*J-6+I) is $T_i(t)$ midway between the $(J-3+I)^{th}$ and $(J-2+I)^{th}$ data points multiplied by the arc length included between the $(J-3+I)^{th}$ and $(J-2+I)^{th}$ data points. The multiplication by the increment of arc length factor facilitates integrations over the source and field regions.

If KL $\neq$ 0 and if RH(1) is not zero, the body of revolution has a rim. The previously defined T(t) nearest the rim will be zero at the rim. Since the ϕ directed current is not expected to be zero at the rim, the T(t) associated with the ϕ directed current nearest the rim was changed to 2 at the rim. This amplitude 2 makes the function linear in t when the points t_j in question are equally spaced. The logic between statements 74 and 78 represents the functions associated with the ϕ directed current by TR.

Do loop 7 computes the arc length TJ at every other data point along the generating curve. Do loop 8 normalizes TJ for a generating curve of length 10.

Using T and TR to invoke a pulse approximation to the T(t) functions, do loop 44 uses the aperture electric field data to calculate and store in E3 the excitation voltage matrices, (equation (27) of the report[1]). If E3(J) represents excitation in the t direction, E3(J+NM) represents a corresponding excitation in the ϕ direction. Actually if KK $\neq$ 3, there is only one type of excitation and either E3(J) or E3(J+NM) is automatically set equal to zero.

Statement 185 reads the admittance matrix Y from, in this case, direct access data set 6. Do loop 134 calculates the coefficients TI of the current expansion functions by multiplying the admittance matrice Y by the excitation voltage matrix E3. If TI(J) represents a t directed current, then TI(J+NM) represents the corresponding ϕ directed current. Since the admittance submatrices $Y^{\phi t}$ and $Y^{t\phi}$ are zero, the t directed aperture field will excite only a t directed electric current and the ϕ directed aperture field only a ϕ directed current. Still in do loop 134, the power required to maintain the aperture field is obtained by summing the products of the complex conjugate of a coefficient of a current expansion function with the corresponding excitation voltage matrix element. The power associated with the t directed aperture electric field is put in P1 and the power associated with the ϕ directed aperture electric field in P2. Since only the real part of the complex power is required to normalize the gain, neither P1 nor P2 are defined to be complex variables. P1 and P2 are written just after do loop 134. The sample printer output for the cone sphere data came from an

earlier version of the program which printed P1 and P2 according to

```
WRITE(3,169) P1, P2, P3
169 FORMAT(1X,7E11.4)
```

where P3 was just the constant $4\pi/k^2\eta$. If KK $\neq$ 3, either P1 or P2 is zero. For some problems with aperture excitation very near the poles of the body of revolution, P2 was negative. This apparent error is due not to the method of moments itself, but to the approximations made in obtaining the source and field integrals.

Do loop 9 calculates complex numbers E1 and E2 whose magnitude is the square root of the gain by pre-multiplying the matrix of current coefficients TI by the measurement voltage matrices VVR previously supplied by the subroutine PLANE. The proper normalization is obtained in statements 190 and 191. E1 and E2 at 1 and NT are expected to be zero. Just to be definite, the 4 statements before do loop 139 assign the phase 0 to E1 and E2 at 1 and NT. The magnitude of E1 squared is the gain associated with the t directed aperture electric field and the magnitude of E2 squared is the gain associated with the ϕ directed aperture electric field. Since the measurement voltage submatrices $R^{\phi\theta}$ and $R^{t\phi}$ are zero, the t directed electric current will excite only a θ directed far field and the ϕ directed current only a ϕ directed far field. Do loop 139 converts the coefficients TI of the current expansion functions to actual currents per unit length by dividing by the cylindrical coordinate radius RH.

After do loop 139, the remainder of the program is devoted to printing and plotting the electric currents and gains. The currents are printed in either do loop 140 or do loop 143. These currents in amperes per unit length are independent of ϕ and possess real and imaginary parts. The gains are printed in either do loop 156, 159 or 167. In the heading, Gθ is the gain associated with the t directed current and Gϕ is the gain associated with the ϕ directed current. Eθ and Eϕ are the square roots of the respective gains. ANG Eθ and ANG Eϕ are indicative of the phases of the θ and ϕ directed electric fields in the far zone.

In do loop 171, M = 1 obtains plots of the t directed current JT and

gain $G\theta$ while M = 2 obtains plots of the ϕ directed current $J\phi$ and gain $G\phi$. Do loop 172 finds X1 and X2, the maximum magnitudes of the real and imaginary parts of the current. Do loop 13 normalizes X1 and X2 to full scale. K3 and K4 represent the real and imaginary parts of the currents and K1 and K2 their corresponding abscissas. CALL REORD(K1,K3,NM) arranges K3 in descending order. The abscissas K1 are arranged accordingly to maintain the original correspondence between K3 and K1. CALL REORD(K2,K4,NM) operates similarly upon K2 and K4. The current is plotted in do loop 20. One line is printed for each J. Data is plotted on a given line only if the ordinate of the data is greater than or equal to the ordinate of the line. If some data is out of range, that which is too large accumulates at the top of the plot while that which is too small is ignored. Do loop 80 prepares the gain to be plotted on a logarithm scale via K3 and K1. CALL REORD(K1,K3,NT) arranges K3 in descending order while still keeping track of K1. The gain is plotted by do loop 87. At the end of the program execution is transferred back to read statement 50. If there is another set of punched card data, the program recycles. If not, execution stops.

Let NP be either the original NP of the data if the generating curve does not close upon itself or 2 plus the original NP of the data if the generating curve closes upon itself. When NP > 43 or NT > 73, some variables require larger dimensions. These variables are listed along with their minimum dimensions.

```
COMPLEX Y(4*NM*NM), VVR(2*NT*NM), TI(2*NM),
     E3(2*NM), E1(NP), E1(NT), E2(NP), E2(NT)
COMMON R(NP-1), ZS(NP-1), SV(NP-1), CV(NP-1),
     T(4*NM), TR(4*NM)
DIMENSION RH(NP), ZH(NP), DH(NP-1), TJ(NM), THR(NT)
DIMENSION K1(NM), K1(NT), K2(NM), K3(NM), K3(NT), K4(NM)
```

Here, as in the main program, $NM = \frac{NP-3}{2}$. The variables E1,E2, K1, and K3 serve a dual purpose. The common statement in the subroutine PLANE should be exactly as it is in the main program.

VII. BACKSCATTERING, OBLIQUE INCIDENCE

This program computes the backscattered field and monostatic radar cross section for a conducting body of revolution excited by a plane wave from an arbitrary direction of incidence. The current is also found but not printed out. The input consists primarily of NP points defining the body contour plus the [Y] matrices for all modes n satisfying (33). The output consists primarily of the backscattered field and monostatic radar cross section patterns. The cross section patterns are graphed by a printer plot routine. The program listing plus sample input-output data are given in Appendix D.

The subroutines PLANE and REORD are exactly the same as the ones in the program concerning scattering for axially incident plane waves.

Punched card data is read early in the main program according to

```
50  READ(1,51, END = 52) KK, NP, NT, BK
51  FORMAT(3I3, E14.7)
    READ(1,53)(RH(I), I = 1, NP)
    READ(1,53)(ZH(I), I = 1, NP)
53  FORMAT(10F8.4)
```

The punched card data for the backscattering program is the same as that for the program concerning scattering for axially incident plane waves except that NN is replaced by KK. For oblique incidence, the R_n's of equations (77) and (81) of the report[1] are considered for only n = 0,1,2···KK-1. Up to and including do loop 8, the programs for backscattering and for axial incidence are essentially the same.

Do loop 42 initializes E1, the measurement for a θ directed transmitter and a θ directed receiver, and E2, the measurement for a ϕ directed transmitter and a ϕ directed receiver. When both transmitter and receiver are located at $\phi = 0$, there are no $\theta\phi$ or $\phi\theta$ polarization components. For the $\theta\theta$ and $\phi\phi$ polarizations, $\tilde{R}_{-n} Y_{-n} V_{-n} = \tilde{R}_n Y_n V_n$ so that the measurement must be multiplied by an extra factor 2 if $n \neq 0$. Inside do loop 40, the subroutine

PLANE is called upon to provide VVR, the receiver voltage corresponding to R_n for n = KK-1. From the KK^{th} record of data set 6, statement 127 reads the admittance matrix Y_n for the same $(M-1)^{th}$ mode. Each L of do loop 41 denotes a different polar angle θ. For transmitters in the direction θ from an origin near the body of revolution, do loop 3 puts the currents in E3 and E4. The transmitter voltage matrices necessary for computation of the currents have been abstracted from the receiver voltage matrices VVR by merely changing the sign of the elements corresponding to $R^{\phi\theta}$ and $R^{t\phi}$. Do loop 43 adds the measurements $\tilde{R}_n Y_n V_n$ to E1 and E2. Toward the end of do loop 41, SIG $\theta\theta$ and SIG $\phi\phi$ along with their square roots MAG S$\theta\theta$ and MAG S$\phi\phi$ are printed. SIG $\theta\theta$ and SIG $\phi\phi$ are echo areas per square wavelength (σ/λ^2) obtained by squaring the product of E1 or E2 with P1. P1 is the constant $k^2\eta/2\pi^{3/2}$ defined earlier in the program just after do loop 1.

The fixed point ordinates K3 and K4 and abscissas K1 and K2 appearing in do loop 80 facilitate plotting the echo areas per square wavelength on a logarithm scale. Do loop 80 also repeats the final printing of the echo areas per square wavelength. Statements 14 and 15 arrange K3 and K4 in descending order and do loop 87 plots the echo areas per square wavelength in the same way that the bistatic scattering cross sections were plotted in the program for axially incident plane waves.

If NP > 43 or NT > 73, most variables require larger dimensions. The affected variables are the same as those of the same name appearing in the program for axially incident plane waves except E3 and E4 which must be dimensioned at least as large as TI was in the program for axially incident plane waves.

13. ABSTRACT

The problem of electromagnetic radiation and scattering from conducting bodies of revolution, both loaded and unloaded, is considered. The solution is obtained by the method of moments applied to the integro-differential equation, and is expressed in terms of generalized network parameters. Computer programs are given for plane-wave scattering and for radiation from apertures. The programs are valid for solid bodies, zero thickness conductors, and bodies with points and edges. The solution for planar bodies is also a solution for diffraction through apertures in a conducting plane, according to Babinet's principle. Representative computations are given for scattering and radiation from disks, washers, toroids, hemispheres, and cone-spheres.
